Acerca de este libro

Esta es una copia digital de un libro que, durante generaciones, se ha conservado en las estanterías de una biblioteca, hasta que Google ha decidido escanearlo como parte de un proyecto que pretende que sea posible descubrir en línea libros de todo el mundo.

Ha sobrevivido tantos años como para que los derechos de autor hayan expirado y el libro pase a ser de dominio público. El que un libro sea de dominio público significa que nunca ha estado protegido por derechos de autor, o bien que el período legal de estos derechos ya ha expirado. Es posible que una misma obra sea de dominio público en unos países y, sin embargo, no lo sea en otros. Los libros de dominio público son nuestras puertas hacia el pasado, suponen un patrimonio histórico, cultural y de conocimientos que, a menudo, resulta difícil de descubrir.

Todas las anotaciones, marcas y otras señales en los márgenes que estén presentes en el volumen original aparecerán también en este archivo como testimonio del largo viaje que el libro ha recorrido desde el editor hasta la biblioteca y, finalmente, hasta usted.

Normas de uso

Google se enorgullece de poder colaborar con distintas bibliotecas para digitalizar los materiales de dominio público a fin de hacerlos accesibles a todo el mundo. Los libros de dominio público son patrimonio de todos, nosotros somos sus humildes guardianes. No obstante, se trata de un trabajo caro. Por este motivo, y para poder ofrecer este recurso, hemos tomado medidas para evitar que se produzca un abuso por parte de terceros con fines comerciales, y hemos incluido restricciones técnicas sobre las solicitudes automatizadas.

Asimismo, le pedimos que:

+ *Haga un uso exclusivamente no comercial de estos archivos* Hemos diseñado la Búsqueda de libros de Google para el uso de particulares; como tal, le pedimos que utilice estos archivos con fines personales, y no comerciales.

+ *No envíe solicitudes automatizadas* Por favor, no envíe solicitudes automatizadas de ningún tipo al sistema de Google. Si está llevando a cabo una investigación sobre traducción automática, reconocimiento óptico de caracteres u otros campos para los que resulte útil disfrutar de acceso a una gran cantidad de texto, por favor, envíenos un mensaje. Fomentamos el uso de materiales de dominio público con estos propósitos y seguro que podremos ayudarle.

+ *Conserve la atribución* La filigrana de Google que verá en todos los archivos es fundamental para informar a los usuarios sobre este proyecto y ayudarles a encontrar materiales adicionales en la Búsqueda de libros de Google. Por favor, no la elimine.

+ *Manténgase siempre dentro de la legalidad* Sea cual sea el uso que haga de estos materiales, recuerde que es responsable de asegurarse de que todo lo que hace es legal. No dé por sentado que, por el hecho de que una obra se considere de dominio público para los usuarios de los Estados Unidos, lo será también para los usuarios de otros países. La legislación sobre derechos de autor varía de un país a otro, y no podemos facilitar información sobre si está permitido un uso específico de algún libro. Por favor, no suponga que la aparición de un libro en nuestro programa significa que se puede utilizar de igual manera en todo el mundo. La responsabilidad ante la infracción de los derechos de autor puede ser muy grave.

Acerca de la Búsqueda de libros de Google

El objetivo de Google consiste en organizar información procedente de todo el mundo y hacerla accesible y útil de forma universal. El programa de Búsqueda de libros de Google ayuda a los lectores a descubrir los libros de todo el mundo a la vez que ayuda a autores y editores a llegar a nuevas audiencias. Podrá realizar búsquedas en el texto completo de este libro en la web, en la página `http://books.google.com`

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.

+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

Aberdeen and Kirkwall, Improved Telegraphic Communication Between, 151.
Abney, Capt., Luminosity of Coloured Surfaces, 450.
Accidents, 397, 418, 458.
Accumulators, *see* BATTERIES, SECONDARY.
Acoustoming Society, 378.
Acheson, E. G., Influence of Condenser on Disruptive Discharges, 80.
Acme Electric Works, 357.
Advertisements of Lamps, 378.
Aeration Currents, 59.
Africa, West Coast of, Cables on, 357, 417, 448.
Allen and Co.'s Works, 357.
Alloys, Conduction of, Gladstone and Hibbert, 432.
Alloys for Conductors, Weston's New, 112.
Alloys, Increase of Resistance on Fusing, 517.
Alternate Currents, Electrolysis by, 69, 298.
Alternate Currents and Electrolytes, 152.
Alternating *v.* Continuous Currents, Brown and the Dog, 135, 168, 171, 317.
Alternate *v.* Direct Currents, Last but not Least, 278.
Alternating Currents Abroad, 193.
Alternator, Mordey's, 116.
Aluminium for Cast Iron, 238, 278, 303.
Aluminium, Electrolytic Production of, 257.
Aluminium, Reduction of, The Cowles' Process, 224, 292.
Aluminium, Reduction of, Hérault's Process, 303.
America, Tariff on Books, etc., 317.
American Fun, 473, 494.
American Gas-Light Association, 419.
American Institute of Technology, 520.
American Patents, 2.
American Plant, Importation of, 337.
Americans, The, Use Them, 33.
Ammeter for Minute Currents, 192.
Ammeter, Schuyler's, 430.
AMMETERS (*see also* METERS).
Ampère, A Statue to, 297.
Anderson, W., 20-Ton Travelling Crane, 331.

ANGLO-AMERICAN BRUSH COMPANY—
Almanac, 518.
Awards to, 438.
Business of, 338.
Employés' Excursion, 25.
and Incandescent Lamp Litigation, 53, 54.
Meetings, etc., 315.
Works, 114.

Anglo-American Telegraph Company, Meetings, etc., 65, 105, 335.
Animal Electricity, 193.
Antilles Cable, The, 151.
Appointments, 45, 67, 109, 131, 297, 337, 357, 378.
Apprenticeship, 298.

ARC LAMPS—
and Astronomers, 45.
Central Station, 468.
Cut-off, 337.
First use of, 308.
on Incandescent Circuits, 298.
Pollak's, 14.
Rule for Height of, 235.
for Sea-Bathing, 131.

Arcs and Sparks, 378.
Architects and Electric Lighting, 32.
Armature Protectors, 111
Armature, Schuyler's, 329.
Army Signalling with Incandescent Lamps, 109.
Artesian Well used for Driving Dynamos, 133.
Artistic Fittings for Electric Lighting, 6, 157, 499, 519.
Asia, Central, Telegraphic Extension in, 257
Atlantic Cable Broken, 257, 277.
Atlantic Cable Tariffs, 110, 129.
Atlantic Cables, New, 457.
Atom, The Charge on the, J. Enright, 95, 122, 136.
Australia and Canada, Cables between, 397, 428.
Australasian Electric Light Company, Meetings, etc., 414.
Australian Cables, The, W. J. Hancock, 208.
Australian Cables, Interruption of, 1.
Automatic Box Company, Electric, 457, 499.
Ayrton, W. E., Lecture on Power Transmission, 211, 230, 272.

B.

Bailey's Manganese Works, 398.
Baking by Electricity, 278.
Balance, Non-Magnetic, Golay's, 485.
Balancing Moving Parts, 60.
Bankruptcy Notes, 65.

BATTERIES, PRIMARY—
Carbon Plates for, Inexpensive, 379.
Chaperon's Optic, 477.
Clark's Standard Cell, 4.
E.M.F. of Various, 309.
Fabrigi and Farkes' Constant Cell, 2.
Gassner's Success of, 297, 497.
Gassner's and Leclanché's, 226.
Raub's Thermo-Pile, 15.
Schanschieff's, 92, 297.

BATTERIES, SECONDARY—
in America, 89, 478.
Charging Stations, 133, 459.
Charging Switch for, 497.
Christmas Demand for, 477.
Drake and Gorham's, for Lighting, 131.
E.M.F. of Various, 309.
Faure's Improved, 440, 458.
Gadot's, 377.
Grid-making Machine, for, 397.
Julien's Patent, 519.
Large E.P.S. Plates, 438.
Measuring Internal Resistance of, 473.
Reviver for, 298.
Specific Gravity Indicator for, 430.
for Tramcars, 26, 211, 261, 277, 278, 298, 378, 409, 479.
Trollies for, 298.
Waggon run by, 417.
Woodward's, 478.

Battery, A Natural, 319.
Bearings, Hot, Detector for, 33, 37, 56, 78.
Bell, Electric, The Diamond, 283.
Bell, Electric, Sparrow's Nest in, 46.
Bell Telephone Patents, 437.
Bell's Asbestos Catalogue, 301.
Bell's New Cocks and Gauges, 353.
Bells, Magneto, New, 67, 97, 109, 357, 397.
Belts, Driving, J. N. Cooper, 7.

NOTES.

Switzerland.—Andermatt, in Switzerland, is to be lighted by electric light.

Australia.—The Municipal Council of Hunters' Hill, New South Wales, have decided to light their borough with the electric light.

Copper Going Down.—The price for high-conductivity copper has been reduced ½d. per lb., making the present price of Nos. 0 to 20 10½d. per lb.

Killed by his own Servant.—M. Gillet, a telegraphic operator at the Vaise Station, Lyons, was killed by lightning while transmitting a message.

Bournemouth.—Mr. Jennings has supplied and fixed an electro-mechanical water level indicating apparatus between the sea water pumping station and the reservoir towers at Bournemouth, for the Improvement Commissioners.

Montpelier.—The opening of a central station for Montpelier is announced for July 14th. The installation will consist of 50 arc lamps of 1,200 candle-power on the Thomson-Houston system for the public streets, and 2,000 incandescent lamps for private houses.

Personal.—We learn that Mr. James Campbell, having left Messrs. J. H. Carruthers and Co. some time ago, has joined Messrs. Mechan and Sons, of Glasgow, who have large connection with shipbuilding and engineering works, for whom he is opening up an electrical department. Power is to be a special feature of the department.

South Kensington.—The answers to the questions in magnetism and electricity set at the recent examination at South Kensington will be found in the June and July numbers of our contemporary, *Science and Arts*. The answers have been contributed by Mr. Walter Hibbert, lecturer on magnetism and electricity at the Polytechnic Institute.

Halifax Town Council.—At the last meeting of the Town Council, Messrs. England and Foster, solicitors, forwarded an application from the Schmidt-Douglas Electric Lighting Company, making proposals with a view to lighting the principal portion of the town with electricity before the coming winter. The Mayor said he would call a meeting of the Council in committee at an early opportunity to consider the matter.

Solid Petroleum.—Dr. Kaufman, for the Russian Government, has made some experiments with the view of rendering petroleum solid, and therefore more useful as fuel. He has found that an addition of 1 to 3 per cent. of soap to heated petroleum renders it, when cool, as solid as tallow, and looking something like blocks of cement. It is then hard to light, but burns with great heat, and leaves a residuum of about 2 per cent. of black deposit.

Australian Cable.—The Eastern Extension Telegraph Company notifies the interruption of its two cables between Java and Australia. A steamer has been chartered to carry telegrams during the interruption, which will leave Java to-day, and is expected to arrive on the 11th inst. at Port Darwin, whence the telegrams will be transmitted by the South Australian land lines to the various colonies. A repairing steamer leaves Singapore immediately to effect repairs, and it is expected that communication will be restored in about ten days' time.

Book Received.—"Electricity *versus* Gas" is a little pamphlet of 70 or 80 pages, published by Messrs. Swan, Sonnenschein, and Co., and written by Mr. Jno. Stent. It professes to be a popular account of the lighting by means of electricity and by means of gas, the conclusion of the author being that the former must sooner or later entirely supersede the latter. We do not know that the pamphlet contains anything very scientific. On page 57 Sir Henry Thomson should be Sir Wm. Thomson, and London should be Glasgow, according to our recollection of the facts of the case.

Private House Lighting.—We are pleased to see that it is becoming more general to put the electric light into new houses which are being built, the instances of which are daily increasing. We understand that Messrs. Drake and Gorham have put the electric light throughout the whole of the new mansion which has been built by Mr. Kingswell, at Bentley Priory, no other illuminant being provided for. Messrs. Drake and Gorham, who are contractors for the work, have fixed a Marshall steam-engine and boiler, driving an Elwell-Parker dynamo, which supplies current for 57 of their latest type cells.

Edison's Patents.—A great flutter has been caused in electrical circles in America, which we over here do not feel the effect of, in the breakdown in the United States Court of Edison's master lamp patent. This has practically thrown the whole industry—carbon or not carbon, filament or not filament—open to the trade, and has naturally caused great jubilation on the part of the Edison Company's legal opponent—the United States Electric Lighting Company. The earlier patent was taken out in Austria; this has been allowed to lapse, and the Court decides that this failure in the foreign country invalidates the American patent.

Encouragement.—We hear that Mr. Edward Weston—the originator of the Weston system of electric lighting—has just been elected the President of the American Institute of Electrical Engineers. Mr. Weston was born in England in 1850, and when quite young amused himself with Smee's "Elements of Electro-Metallurgy," and such things, describing how to make electrical experiments Soon after sixteen years of age he began the study of medicine at the wish of his parents, did not like medicine, went to the United States in 1870, began work there for the American Nickel-Plating Company, and since has used hands, eyes, and head, and is now near the top.

Electric Door Opener.—A great deal seems to be done with electric door openers in America. As you step on the mat contact is made, the bolt withdrawn, and the door calmly opens before you. We do not remember to have seen these in the various catalogues of electrical sundries we have had submitted to us. There might be an opening for some business in this as well as in many other directions for electric novelties for shop purposes, especially in connection with a good dry cell. We feel sure the public would take up electric novelties of this kind with greater avidity if they were submitted complete in detail, and if little trouble for attention could be guaranteed.

Edison's Troubles.—Thomas A. Edison, the inventor, is now dividing his time between the joys of paternity and experiments upon a new electric flying machine which he has been commissioned by the Spanish Government to make for war purposes. The system will be one of revolving fans, to which power is supplied by means of a wire connecting with an electric dynamo on the earth. The fans are not only to propel, but lift the air ship. Then with a properly

Digitized by Google

equipped car an officer can ascend and take photographs and sketches of the enemy's position, which will give a great strategic advantage to the Spanish commander. Mr. Edison is confident that his experiments will result successfully.—*New York Tribune.*

Weber and Schefbauer's Insulation.—These gentlemen take two or more wires placed at a suitable distance, and cover them with paper strips previously passed through a bath of ammonia oxide of copper. This paper band now bears upon its surface a coating of cellulose. The whole is then forced through suitable rollers, the cellulose of one spiral uniting with that of the next, forming a complete whole. The coated wires are again passed through the copper bath, and then through another pair of hot rolls, the lead coming out dry and smooth. While still warm it passes into a bath of boiling linseed oil, and is again passed through the rolls, which throw out the excess of oil, and the strip is supposed to be perfectly flexible, elastic, and insulated against damp at any rate.

Electrical Patents.—The number of applications for patents in America for electrical appliances is phenomenal. During the week ending May 29, 73 patents were issued from the Patent Office A general sub-division into various recognised departments is interesting, as showing those in which inventors are most busily engaged:—There are 14 patents relating to instruments and devices of measurement and testing, 2 to telegraphy, 2 to the telephone, 3 directly to the motor, 4 directly to the galvanic battery, 4 directly to the secondary battery, 1 to a thermo-electric generator, 26 to dynamos and electric light apparatus and the transmission and distribution of electricity for purposes of light and power, 17 to miscellaneous applications. Among those relating to electric light apparatus, are quite a number covering a whole alternating current system.—*Scientific American.*

A New Constant Cell.—In a communication to the Académie des Science, MM. Fabrigi and Farkas, describe a new constant cell. This cell consists of a small platinum vessel, coated on the inside with a compound having the formula given as $Na_2H_{12}Pt_2O_{11}$, and which is formed by heating the platinum in contact with caustic soda. The vessel is filled with fused caustic soda, maintained in a fluid condition by means of a small gas jet. The positive electrode consists of platinum; the negative one of gas carbon. On closing the circuit, the E.M.F. soon assumes a steady value, as the carbonate of soda produced is continuously eliminated and deposited in a crystalline form on the free surfaces of the electrodes. The E.M.F. depends on the temperature, but the temperature coefficient is so small, that with an ordinary gas flame the E.M.F. may be maintained sensibly constant for several hours. Large and sudden alterations in the external resistance merely cause a momentary change in the E.M.F., which almost immediately returns to its original value.

Heights of Clouds.—The cloud illumination caused by the electric lights of Detroit and Ypsilanti is occasionally so well defined in outline, as seen from this observatory, that it occurred to the director to inaugurate a series of altitude measurements for the purpose of determining the heights of all forms of clouds visible at Ann Arbour after twilight. The central portion of Detroit is about thirty-five miles from the observatory, while Ypsilanti is only 5·8 miles distant. The azimuths of the two cities differ about 30 degrees, so that the conditions for determining the heights of the upper and lower clouds can always be made favourable when the atmosphere is sufficiently transparent. When the clouds are very high, the Detroit illumination is so well defined that the probable error of a single measurement of an altitude is only a few minutes of arc. When the clouds are low, the nearer illumination is well defined, and the farther one either invisible or coincident with the apparent horizon. The greatest and least heights recorded up to the present time are respectively 17,580 and 770ft.—*Amer. Meteo. Jour.*

Electric Fire-Engines.—We are evidently only just waking up to the numerous and extended uses the electric current can be put to when a full and thorough distribution of power is possible by means of mains. Not only has it been proposed to apply permanent motors for the pumping water for house supply, but an inventor is to the fore with an electric fire-engine. Connection could be made on the incandescent circuit to run a motor for throwing the water. Double electric cables and a motor force-pump will be all the machinery required, if proper means are secured for electric connections or fire-plugs. The great advantages claimed for the electric fire-engine are that it can be instantaneously started up at full speed; that it is much lighter than a steam fire-engine of equal power; that it costs one-third less; that it is safer and easier of control; that it is noiseless in its operation; and that it is economical. Where there is no general electric distribution, it might prove practicable to run the motor both for carriage and for pumping by means of storage batteries, sets of which could be kept ready charged at the fire-engine station.

Great Chances for Three Inventors.—Prof. R. H. Thurston, in the May *Forum*, states that the world is awaiting the appearance of three inventors, greater than any who have gone before, and to whom it will accord honours and emoluments far exceeding all ever yet received by any of their predecessors. The first is he who will show us how, by the combustion of fuel, directly to produce the electric current: the second is the man who will teach us to reproduce the beautiful light of the glow-worm and fire-fly, a light without heat, the production of which means the utilisation of energy without that still more serious waste than the thermo-dynamic now met with in the attempt to produce light; while the third is the inventor who is to give us the first practically successful air ship. The first two of these problems are set for the electrical engineer, and we may be pardoned excess of faith should it prove to be such, when, contemplating the enormous gain to humanity which must come of such inventions, we look confidently for the genius who is to multiply the wealth of the world to an extent beside which even the boon conferred by the creators of the steam-engine and the telegraph will not appear overshadowing. When this inventor comes forward, and most probably not till then, it is very likely that we shall see steam superseded by a rival.

Luxurious Cars.—The Chicago, Santa Fe and California Railway, says the *National Car Builder*, have running between Chicago and Kansas City a service of vestibule trains, the cars of which are large and commodious, built in the most substantial way that skill and experience could devise, decorated without regard of expense with rare artistic taste, and furnished with the most luxurious equipment that could be conceived as likely to conduce to the comfort and safety of passengers. Each train consists of nine cars, one baggage, one mail, one second-class, two first-class, combined parlour and smoker, one dining and two sleeping cars. The whole train is vestibuled from the baggage car

Digitized by Google

to the rear. The entire train is heated by steam from the locomotive, and lighted by electricity supplied by a dynamo run by a Brotherhood engine placed in the baggage car and supplied with steam from the locomotive. Storage batteries are also carried on the cars for providing a supply of electricity when from any cause the rest of the train is parted from the baggage car. The train is fitted up with the new Westinghouse quick-acting brake and the pneumatic train signal, but it has an electric system of signalling besides. The trucks have 42in. Allen paper wheels. The Miller coupling is worked by a ratchet arrangement placed on the steps of each car, and the hand-brake is geared to supply the necessary power should hand-braking be necessary.

Efficiency of Dynamos.—A simple and practical workshop method of estimating the commercial efficiency of dynamos is pointed out by *L'Electricien*, as used by M. Hippolyte Fontaine, and given in the third edition of his work on electric lighting. Until the invention of a thoroughly practical and reliable transmission dynamometer, this method may be usefully employed to verify the efficiency of identical machines; it requires merely the use of an ammeter and a voltmeter properly graduated, but not necessarily absolutely accurate. The two dynamos are placed one behind the other, and connected together by a belt; the first receives the current of a third dynamo driven by any engine, the second produces a current closed through an easily regulated resistance. The variable resistance is altered until the two currents are equal. Calling I the common current of the two currents, E the difference of potential at the terminals of the machine acting as motor, and E′ that of the machine acting as generator, the power given is evidently equal to E I, and the power produced is equal to E′I. The efficiency of the whole is, therefore, equal to $\frac{E'}{E}$; and the probable average efficiency of each, if they are similar, is $\sqrt{\frac{E'}{E}}$ on condition that the two machines have the same power as motor and as generator. This method is simple, rapid, accurate, and is easily and directly applicable in workshops for the construction of dynamos.

Subways.—Mr. Albert R. Ledoux, at the close of an article in the *Evening Post* on English and Continental practice in this matter, summarises European practice as follows: The whole situation to-day in Europe, including Great Britain, may be summed up as follows: Telephone service, overhead, small copper wires on neat standards upon housetops, owners compensated for use of roof. Poles only allowed where roof service is impossible. Telegraph service, largely underground in England, and on housetops elsewhere. Electric (arc) light service practically all overhead. So complex and intricate a tangle as the subway problem in New York is not even dreamed of in Europe, much less solved. With our growing electric light service, our district-messenger calls, and, above all, our great telephone system; with our network of gas and water and steam pipes in the street, we have a problem that we must work out practically alone—unaided by European experiences. Radiating from our metropolis, like the threads of a gigantic spider's web, including and connecting neighbouring cities and growing towns, and even distant cities, already there stretches a network of wires along which throb the impulses of our commercial life. We think the problem of their location difficult to-day; what will it be when every man has a telephone in his house; when gas light within, as well as without, gives way to the electric light; when our streets must yield yet more room for fuel-gas pipes, larger water-mains, &c., &c.—what shall then be done?"

What Shall We Read?—Under this title, Mr. T. D. Lockwood contributes an article to our contemporary, the *Electrical World*. In it he considers the technical newspaper, and upon this subject we quote the following remarks:—"It is right to say that an electrical library, no matter how complete, cannot take the place of the electrical newspaper. Every man engaged in applying electricity should make a point of taking that one of the weekly electrical periodicals which, after due inquiry among his associates, he decides to be the best adapted to his wants. If he can afford more than one, he ought to take one English and one American periodical; or if his treasury be sufficiently plethoric, he will find it advantageous to subscribe for all of the American weekly and monthly electrical periodicals, and also for the British *Electrical Review*, *Electrician*, or *Electrical Engineer*. Unless he be a linguist, it would not be advisable to take a technical paper printed in a foreign language, because the main portion of the electrical news of the day is to be found in all of the journals printed in the English language; while any subject of general interest will likewise be certain to be found in at least one of them. I have considered it expedient to speak first of electrical journals, because this is a generation that necessarily, to hold its own, must act in the living present; and though a man working now in electricity were thoroughly versed in the archæology and antiquities of the science, and though to this knowledge he add an extensive acquaintance with college text-books, this all amounts to very little if he fail to keep himself fully informed of the progress of the day; for history in electricity is now a matter of days, and is more rapidly made than ever before. The only way, therefore, to hold one's own is to peruse and study the journals. But in addition to these, if we desire to have full information—in short, if we desire to excel—we require something more. It is true that the number of books is legion, but I imagine that half-a-dozen of well-chosen books will be all that a young man needs at the outset, and they will form a good nucleus round which a library may be built by slow but solid accretions.

Telephone Catalogue.—We have received the very complete catalogue of telephonic requirements issued by the Consolidated Telephone Construction and Maintenance Company, Limited, 109, Farringdon-road, E.C., the sole licensees for the Bell, Edison, Blake, and Gower-Bell systems for the United Kingdom. Apparatus is therein described and fully illustrated, suitable either for a private installation of a pair of telephones or a fully-developed exchange, with all accessories, for which the company undertake contracts and, if required, negotiate for concessions. The "consolidated" magneto telephone, and "consolidated" battery telephone, are shown, together with the Gower-Bell or ordinary Post Office pattern. Diving telephonic apparatus, fitted to diver's helmet, with small box and battery for shore end, is largely used by the Admiralty. The Gower-Bell portable telephone for field or military purposes, contained in a small square box, and a similar form for miners, are convenient forms of the combined apparatus. The operator's receiver has been designed to leave the hands perfectly free, and is mounted on a strop or band, which goes over the head and allows the receiver (or two if preferred) to come close over the ear. This form is largely used in Lisbon by subscribers who wish to hear the

Digitized by Google

opera without leaving their residences, and is greatly appreciated. The Bell-Blake magneto and battery telephones are forms supplied to subscribers by the United Telephone Company of London and their subsidiary companies. Magneto call-bells, operators' telephones, exchange switch-boards, and annunciators, each have their department illustrated. The automatic call box, set in motion by the weight of the necessary coins, is very popular, and its use is extending. The call-box is placed under the care of some local and influential tradesman. The person wishing to communicate places the required coppers in the slit, and the electrical contact is then made automatically with the Telephone Exchange, who connect as desired, and the current is cut off automatically after a certain period of time. A small magnetic generator is shown for use with call-bells, which is also used for testing electric light circuits. The Consolidated Company also supply "Simplex" arc lamps, single or double for parallel working. For greater convenience in telegraphing, a special telegraphic code is given at the end of the catalogue.

Electric Lamp-Posts.—We note in a report from Berlin, with reference to electric lighting in that town, that architects have been invited to send in designs for lamp-posts. This is, we fully believe, a step very much in the right direction. On a new town installation being put down the technical journals, of course, will treat most fully of its electrical character, the ingeniousness and stability of its engineering part; but intending central station installers had better be quite aware that for the public quite as much will depend on the design of the lamp-posts as upon the proper arrangement of the distribution. The comparative strength of the light and the proper reflecting arrangements are also points on which every town councillor and local architect will certainly have his own opinion, though as to whether a friction clutch or an extra gas-engine be employed he is not able to be so sure. If in the same manner, at the outset the central station engineers clearly acknowledge and lay themselves out for the proper pleasing of the eye of the *cognoscenti* in the matter of lamp-posts, they will go a long way to pave the way for great future extensions of the system. From some of the specimens we have seen, this point seems to have escaped altogether the business acumen of the original promoters of the electric lighting industry. Large iron tubes, with coarse tee-pieces of iron barrel, have been made e'er now to do duty as electric lamp-posts in a permanent installation. Nor would it be much better to take the designs of manufacturers of gas-lamps and get them to modify these designs for gas. As a rule there is very little really artistic about them, and the modification would not improve the matter. We in England at this present moment are not without talent which will enable us to produce something really commendatory to all, at a price not far in advance of modified gas lamps; and the step the Berlin authorities have taken is one in the right direction. There are, we are quite sure, many quite able to design such fittings among the architects, men who would be able to put real beauty and proportion into these standards, which are probably henceforth to be landmarks in every street. Let us imagine for one moment, how such a desideratum would have been treated in the palmy days of Venice, Verona, and Florence, and, reflecting on the remark recently made by Sir Frederick Leighton, that English art is, at least, as great as Italian, let us also hope that English municipal and engineering enterprise is at least as good as German, and let us try and see our way to the fulfilment of this requirement.

Magnetic Perpetual Motion.—As the question of perpetual motion by means of a magnetic insulator is continually cropping up in the ingenious minds of students, we give the following answer to a letter addressed to the editor of the *American Machinist* upon the question, as to whether magnetic force acts through every known substance. The letter disagreed with the statement that there was no magnetic insulating substance known, and stated that it is a fact that magnetic force will not act across a screen of iron or other magnetic substance, as nickel, cobalt, and a few other substances, and referred for a statement of this, and description of experiments to prove it, to Prof. Silvanus Thompson's "Elementary Lessons on Electricity and Magnetism," p. 77. In answer the editor says: "The statement in the book referred to says that 'a magnet enclosed in a hollow sphere of iron is unaffected by outside magnetic influence.' This, however, is not due to the iron being an insulating substance at all, because it is not an insulating substance. Two magnets, between which a sheet of iron is interposed, still attract each other, and will do so through any known substance, through a flame, through any known gas, or through a vacuum. The fact that a sphere of iron acts in this way seems to be due to a balancing or absorption of the magnetic force, due to the form in which the metal is disposed, rather than to the character of the metal itself—a fact which seems plainly demonstrated when we consider that if the half of the sphere furthest from the outer magnetic force be removed, the force will act through the other half. It will seem from this, that in the sense in which the original question was meant our answer was correct. Numerous individuals have thought that they could produce perpetual motion by mounting two permanent magnets at the ends of levers in such a way as to be attracted toward each other, and by their movement cause a thin sheet of insulating material to be interposed, thus cutting off the attraction, and causing the magnets to recede from each other by the action of gravity, or of a spring; this action in its turn removing the insulator, and allowing the magnets to again attract each other, thus producing a motion which would go on indefinitely without the expenditure of external forces. Among all the many schemes to produce perpetual motion, this perhaps seems upon the face of it to be the most feasible. But, as if Nature has deliberately calculated to defeat every plan to produce such a motion, she fails to furnish the required insulating substance: at least it has never been and we believe never will be discovered." We might also point out that when two permanent magnets have attracted each other, their molecules have lost a certain amount of kinetic energy, and are no longer such strong magnets. To give them back this energy it is necessary to forcibly separate them; this action returns the magnetism by the action of elbow grease or other mechanical power, and any substance, insulating magnetically, even if found, in order to make such a machine work, would also have to contain the power of returning the lost magnetic energy, which is not what we should call probable.

Clark Standard Cells.—Notwithstanding, says Mr. D. Woodman in the *Electrical World*, the exceedingly satisfactory results obtained by Lord Rayleigh, and the high estimate placed by him and others on the accuracy and value of the Clark standard element, the notion prevails to a considerable extent that his results are so difficult of duplication as to make a reliable Clark cell more a scientific curiosity than a *practical* standard E.M.F. Taking up the subject about a year ago at the request of Mr.

Digitized by Google

J. W. Howell, of the Edison Lamp Company, a number of cells were made up which have been compared with each other on an average of once a week since the fourth day after their completion, without at any time recording a difference in their values of as much as $\frac{1}{10}$th of 1 per cent. Six parts in 8,000 has been the extreme difference, and usually not over three or four parts, while agreement is frequently so close that the slight variations are not more than possible errors of reading, or probable variations in temperature. 1deg. C. causes a variation of eight parts in 10,000, or slightly less than $\frac{1}{10}$th of 1 per cent., according to determinations made by Rayleigh. Although the differences among many of his cells were stated at less than two parts in 10,000, he sums up his experience in the statement that he "believes that cells properly made will not vary, at ordinary temperatures, more than $\frac{1}{1000}$ part of their value—*i.e.*, not more than one tenth of 1 per cent." This has been considered a satisfactory standard to attain in the work of the past year. As to whether differences under one-tenth of 1 per cent. are enough to unfit the cell for any particular work, the electrician can decide for himself, and undertake the preparation of a standard of greater accuracy for special cases. But for work of a very considerable degree of accuracy such small variations will not be of importance. A battery of six standard elements prepared for Mr. Edison's laboratory at Orange, one month after being set up, differed two parts in 8,000, and up to date no greater difference has been reported. Its convenience of form and permanence, when properly prepared, are the reasons why its employment would have been very general but for the shaken confidence resulting from disagreement of cells prepared by different persons, and want of permanence in many of those sold commercially. Non-transportability except by hand has also been to some extent a drawback, and a modification whereby this difficulty has been overcome will be an additional point in favour of convenience. As to difficulties of preparation, not the least is the mechanical one of a satisfactory seal against evaporation, which is the only enemy to otherwise well-prepared cells. The remaining difficulties are purely chemical, and it is neither unfair to the amateur in chemical work, nor awarding too much to the chemist, to say that these difficulties are not likely to be appreciated or obviated by those without some training in exact chemical work. Not only is it difficult to purchase strictly pure chemicals, but also to prepare them, and where one article purchased may be all that could be desired, another will introduce a disturbing impurity; so that without analysis no purchased article can be safely used, unless one is willing to undertake the tedious and expensive method of trial and failure until something sufficiently good is obtained.

The British Association.—A meeting of the Executive Committee was held at Bath last Friday under the presidency of the Mayor. Amongst those present were the Rev. Canon Brooke, Rev. H. H. Winwood, Dr. Tuckett, Mr. Murch, Mr. R. Porter, Mr. Norman, Mr. H. Holland Burne, Mr. R. S. Blane, Mr. J. S. Bartrum, Mr. F. Mason, Mr. John Stone, Mr. W. G. Wheatcroft, Mr. J. S. Turner, Mr. Milsom, Mr. Daubeny, Mr. Plowman, Mr. R. D. Commans, Mr. R. King, Mr. W. C. Jolly, Mr. H. W. Freeman, Mr. Horner, Mr. Braham, Mr. Jas. Williams, and Mr. J. L. Stothert, Mr. W. Pumphrey and Mr. B. H. Watts (hon. local secretaries), and Mr. Norfolk (assistant secretary). It was reported that the Reception Committee required £1,750. This covered the expense of erecting and fitting up the reception room in Alfred-street, the hire of the Assembly Rooms, and also the expenses of fitting up the drill hall. It did not include the cost of messengers. A canvass of lodging-house keepers had been made with the view of ascertaining what accommodation they had to offer. A circular had also been drawn up, and would be sent out shortly, asking private citizens whether they would be willing to entertain any of the visitors. Mr. Stothert said he had been in London during the past day or two conferring with Mr. Aitchinson, the general secretary. A meeting had been convened, when Mr. Aitchinson would attend in person and give them the benefit of his experience in these matters. Mr. Wallace Arnold roughly estimated that the lodging-house keepers would be able to accommodate 2,000 visitors. Mr. Stothert said the subscriptions were coming in to some extent, and the newspapers would this week contain a second list of subscribers. They were not up to the sum they wanted by a good deal, and from what he saw he thought that the expenses, instead of diminishing, were likely to go the other way, therefore it was very important that they should have as much aid as they could. Mr. Murch, chairman of the Finance Committee, found that the estimated expenses already made up amounted to £2,890, without contingencies. Upon the application of Mr. Turner, the sum of £75 was granted for the preliminary expenses in connection with the various excursions. The Mayor said he had written to the Marquis of Bath asking him for permission to make arrangements for an excursion to Longleat, and he had no doubt but that permission would be accorded.—At Newcastle, on Tuesday, a meeting of the Local Committee in connection with the visit of the British Association to Newcastle in 1889, was held in the Mayor's Chamber, Town Hall, Dr. Phillipson presiding. Amongst those present were Prof. J H. Merivale (hon. secretary), Prof. Lebour, Prof. Bedson, Dr. Spence Watson, Dr. Oliver, Mr. Martin, Mr. W. G. Laws, Mr. Dinning, Mr. Thos. Hunter. The three editors of the Local Guide are as follows: Historical section, Dr. T. Hodgkin; natural history, Prof. Lebour; industries, Mr. Wigham Richardson. The object of the guide is to put into the hands of visitors a brief sketch of the industries, natural history, and general history of the Northern counties. The minutes of the Local Guide Sub-Committee were approved. The next business was to consider the calling of a public meeting. The Mayor was willing to place the Council Chamber at the disposal of the meeting. Prof. Merivale thought they should have the Town Hall if they could fill it. Perhaps they should have another stage before calling a large meeting like that. It would be necessary to have two meetings before the Bath meeting on September 5th—one, a public meeting to elect a General Committee, and a meeting of the General Committee to transact certain business. They would have to inform the Bath meeting who was appointed local secretary and treasurer. The secretary would have to go to Bath to pick up what information he could. The 10th of July, in the Council Chamber, as the date for the public meeting, at four in the afternoon, was agreed to. The meeting agreed upon a list of local corporate, literary, scientific, and professional bodies who should be asked to nominate members of the Local General Committee. It was agreed to recommend that the minimum subscription for members of the General Committee should be two guineas. It was agreed that there should be a paid secretary at a salary of £100 a year.

ARTISTIC FITTINGS.

III.—Binswanger and Co.

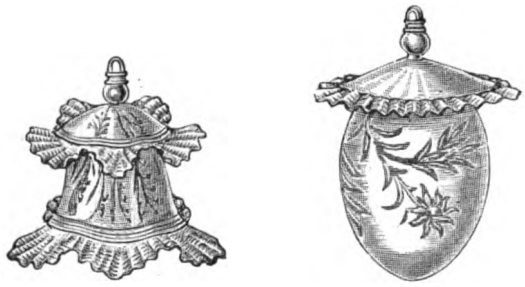
In contradistinction to the d scriptions we have previously given, and shall hereafter give, of artistic fittings, definitely designed and manufactured primarily, one may say, for their artistic effect, and the cost of which is reduced only to within the limits of a fair profit on the expense and time employed in manufacture, we give this week specimens of fittings avowedly designed from the other point of view —namely, to be supplied as cheaply as possible in quantities, and invested with as much artistic merit as possible, allowing the fair margin of profit.

Flower Pattern Etched Shades.

Taking the point of view of cheapness first, and as much artistic look as can be obtained at the same time, it has long been evident to electrical engineers that the simple hanging cord pendant makes the simplest, cheapest, and prettiest fitting for the electric light. There are certainly many positions in considering the electric light as to be applied in lighting, in which cord pendants would not be sufficient ornamentation—the space requires more filling, and the taste, together with the pocket of the owners, inclines towards something more spacious and more ornate. But there is always this to be said about cord pendants, they never look like gas-fittings. Many electric light fittings are not yet free from

Cut and Etched Shades.

the thraldom of the designs of gas-pendants, and, notwithstanding the difference of the globes and shades, can still, without much difficulty, be taken for ordinary gas-pendants. This cannot be the case at all with cord pendants hanging by a light suspension from the ceiling; and this is often a great point with the happy owners of the only safe illuminant. They want it to be clearly known and noticed that they have invested therein. On both counts, therefore, it is evident that as electric light extends, whatever may be the case with more elaborate fittings, cord pendants will always have a great demand.



Etched Shades with Glass Mantle.

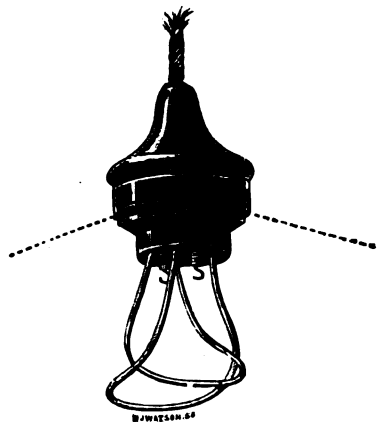
Messrs. Binswanger and Co., of Great St. Thomas Apostle, trading under the name of the General Electric Co., have for some considerable time devoted their attention to the large supply in quantities of various electrical requirements in the way of fittings, and have made a special point of the question of cord pendants. We illustrate this week some of the special designs which this firm have introduced; many of these will prove very useful to installers of electric lighting on the lines we have pointed out.

One of the chief difficulties which have laid in the way of a more extended and cheapened use of small and pretty fittings, has been the want of uniformity, or of a standard, in the sizes of the fittings employed. For instance, in the matter of glass shades, it has been up till now the habit with these articles to make them with all and sundry sizes of neck openings. Some shapes will have 2in. openings, others $2\frac{1}{4}$, $2\frac{1}{2}$, or 3in., at will and without method. It is most irritating when customers have sent to ask for a certain kind of shade, with, say, $2\frac{1}{4}$in. opening, to find that the shade is in stock, but cannot be sent because the opening is $\frac{1}{2}$ or $\frac{1}{4}$ of an inch too large or too small.

Ribbed Moulded Shade.

Iced Opal Reflector.

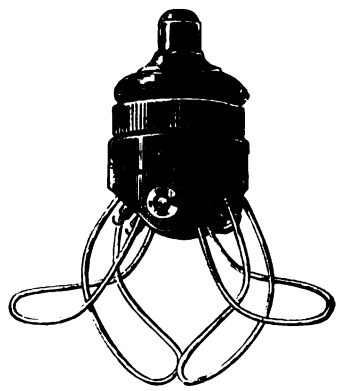
This is certainly a point on which it might be well for the general trade to combine, and arrange for certain most convenient standard sizes. Pending any such united action, Messrs. Binswanger, recognising the desirability of having one standard opening, have been making all the openings



Standard Holder for $1\frac{1}{8}$in. Opening.

of glass shades for pendants of one size—namely, $1\frac{1}{8}$in., which they have found a size most convenient all round. This will take any ordinary holder with a cap, but they make a standard holder which fits this size glass without flange or cap, and is thus most easy to fit or alter.

A large number of the glass shades for cord pendants are made with various flower pattern designs etched on the



Standard Holder for Two Lamps.

surface of the glass, of which we give several illustrations. These have a subdued and ornamental effect, and are made in various shades of colour—opal, blue, yellow, amber, ruby, and white. Another form which has a very pleasing effect is that of the mixed cut and etched patterns, of which we also give illustrations. The mixture of subdued light with the sparkle of the cut glass is sometimes very effective.

Digitized by Google

Another type of pendant is shown with a double glass shade, the bottom being either a shade or a globe, and having an ornamental glass mantle over. A cheaper form is that of a moulded and ribbed shade, produced in various forms and many colours. The ordinary opal reflector is much improved in appearance when made in iced glass as shown.

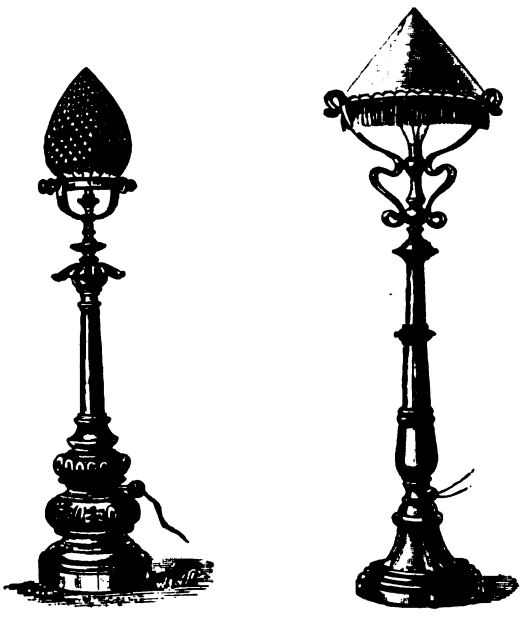


Table Standards.

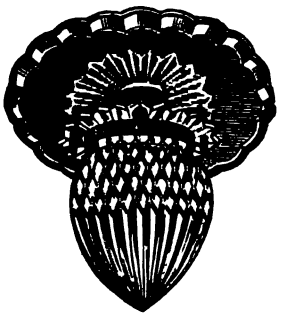
Of table standards this firm make several patterns of neat design and very moderate price; we illustrate two of these—one with a glass and silk shade, and one with cut-glass pine shade. Other fittings are also made with cut glass combined with mirrors, which have a very brilliant effect; when the light is in, the combined reflection and refraction from mirror and cut glass enhances the general effect very considerably. These kind of fittings have been much supplied to coffee-rooms and other apartments for hotels.



Cut-glass Globe and Mirror Reflector.

Throughout, as we have indicated, Messrs. Binswanger have paid special attention to the supply of glass shade electric light pendants in variety, and by the application of business methods for production of large quantities are enabled to supply them at very moderate prices, and we have no doubt will meet with the appreciation from the trade which they aim at in these departments. They have besides given some attention to floral brass fittings, and have lately supplied some very handsome beaten brass fittings of Oriental design in the form of large decorative pots of flowers, fitted with electric light, for two Indian rajahs. They have also several novel electric specialities not coming under the head of artistic fittings, which we hope to illustrate shortly.

NOTES ON BELTS AND BELT-DRIVING.*

BY JOHN N. COOPER.

The importance of this detail in the designing and erecting of any electrical installation or in laying down factory plant, &c., has induced me to bring before your notice a few data which I have recently been collecting, having reference to this subject, in the hope that information I can give will be of use to some of the members present at this meeting.

The requirements of a good belt are: 1. That it shall have great tensile strength. 2. That it shall get a good grip on the pulley. 3. That it shall be made of a material which will have a long life under the specified conditions.

The materials most generally used in the manufacture of machine belts are: Leather from the hides of various animals; cotton hemp, &c., woven into the form of a belt; gutta-percha and indiarubber laid on to a foundation of cotton or some such substance; and in quite recent years the hair of animals, such as the camel and lama, has been woven into belts.

Ordinary leather belts are made from strips cut from the central part of the hide, called the butt. This is the most solid part of the hide when tanned, and the texture is the most uniform. The strips of leather are then joined together, forming a piece of belting. In the process of manufacture the leather undergoes a process of stretching, so that when the belting is put on to any work its stretching is reduced as much as possible.

The size of the butt of an ox-hide is about 4ft. 6in. long by 4ft. wide, and so the strips of which a good belt is made should not exceed 4½ft. in length. If the strips are much longer than this you can, tell at once that some part of the offal has been used, and the belt has been made up of leather of uneven quality—parts of the belt stretching more than others. When cheaper belts are made, a longer strip is cut out of the hide.

Different makers employ different methods of joining the strips together for the purpose of making a continuous length of belting. They all aim, however, at getting a joint which shall be as strong as possible, as pliable and as smooth as the body of the belt, and which, for these reasons, will run over the pulleys without any jerking or unevenness.

A kind of belting which has been used to a considerable extent in electric lighting jobs in this country and in America is made by Mr. J. B. Hoyt, of New York, and is known as "Hoyt's short-lap leather belting." In the manufacture of this belting the butts of oak-tanned hides are used, and the joints are made with very short laps. The scarf joints are then made firm in one of the usual ways—viz., either (1) cemented and then sewn; (2) cemented and riveted with copper rivets; or a combination of the two methods—cemented, sewn, and riveted. In this way a belt is made up having the same side of the leather next the pulley for the whole length.

Another kind of belting well known to electrical engineers is the "Victoria belting." The leather used in the manufacture of this belting is also cut from the butts. The spongy side is then pared away by special machinery, and the whole is reduced to a uniform thickness. This process, the makers claim, does not weaken the belt, and it undoubtedly makes it more pliable. A double Victoria belt is generally used. This is made by cementing two thicknesses of pared leather together, and then riveting through with copper rivets; a double Victoria belt is very little thicker than ordinary single leather belt. The Victoria belt is run with the hair side of the leather next the pulleys.

Messrs. Tullis and Sons, of Glasgow, are working a belt known as "orange tan leather." This belting is made from Highland ox-hides, and is tanned with a preparation of orange, instead of oak bark, which is generally used in tanning. In the process the leather, instead of swelling, as is the case of oak-bark tanning, shrinks and becomes thinner. When tanned, it weighs nearly 50 per cent. lighter than if oak-bark tanned. The breaking strain of belts prepared in this manner is very much greater than that of ordinary tanned leather.

An ingenious method of joining the strips of leather has been invented by Mr. Jardine, of Nottingham. This join has been designed so as to give double the usual surface of contact between the two faces of the leather which has to be cemented together. There is (so Mr. Jardine says) no necessity to either sew or rivet this joint, and, in consequence, the strap is not weakened by cutting away the leather for rivet and lace holes. The belt, of course,

should be run in the direction of the splice, and if this is done it is impossible for the joint to be torn up, as there is no projecting part of the belt to catch in anything.

In making the last joint in a length of belting, so as to make the belt an endless one, the conditions under which the belt is to be used must be taken into consideration. In the generality of cases this joint must be left uncemented, since occasionally it has to be undone to allow of the stretch of the belt being taken up.

Of course, in the case of dynamo-driving we generally have the belt an endless one, as the slack is taken up by moving the dynamo along its rails. Laces tanned with alum are, as a rule, used to join a belt. The lace-holes are pierced in two rows perfectly parallel with the end of the belt, those of each row facing the centre space between the preceding ones. This method distributes the strain on the holes in a fairly equal manner, and so reduces the chance of the lace holes being torn out. In making the joint, care should be taken that the ends are cut square off, or else a crook may be made in the band. There are besides this join any number of other ways. Almost everyone who has charge of belting has fixed upon one particular method which he sticks to, and which in his opinion is preferable to others.

Many mechanical devices have been invented with the express purpose and idea of superseding all lacing. Some of these connections are good, others are far from being so.

I should now like to say a few words on *leather link belting*, with the especial purpose of getting at some information from men who have had experience with it, and who have had full opportunities of knowing its disadvantages as well as its advantages. Link belting, I believe, is preferred by many engineers, for the reason that it runs perfectly true, and it is easily joined up as an endless belt without having to use laces or special fasteners. I, however, think from my own observations that a good cotton or leather belt is superior both in simplicity of working and in results. A link belt cannot be made stronger than a plain leather band of same size.

Again, the links of leather are all strung on to a metal spindle, which is always parallel to the axis of the pulley, and the surface of the pulley is curved. In plain link belting the links are all the same size, and so there is a continual straining and bending of the rivets when passing over the pulleys, so as to enable the belt to get a good grip of the pulley. As soon as the rivets have passed over the pulley they straighten out, and so some work is done in the belt itself. The power necessary to do this work of course must be supplied by the prime motor. Messrs. Tullis, of Glasgow, have considered it worth while to make the link belt arched so as to fit over the crown of the pulley, so that there is no bending strain on the rivets.

Again, the total surface of leather in contact with the pulley cannot be so great in the case of a link belt as in the case of an ordinary leather band, for between each link a certain amount of space must intervene. These spaces may be an advantage rather than otherwise in allowing the film of air which gets carried in between the belt and the pulley to escape, and so enables the leather to get a good firm grip of the iron. This idea of getting rid of the air film has been worked out in another way by Mr. Shepherd; he perforates the rims of his pulleys with a number of small holes, and thus allows the air to be driven out.

Indiarubber and Gutta-Percha Belts are now in use to some small extent, but, as far as I have been able to find out, they do not seem to have met with much success. The advantages claimed for these belts are: They are not affected by wet or steam, or changes of temperatures. The grip they get on the pulley rim is very perfect, since, by the very nature of the belt, it fits itself to all the small inequalities of the pulley. They are uniform in weight and texture, and they run very true. I noticed that Mr. Rankin Kennedy has used a gutta-percha belt on the ss. "Paula," which he has lately fitted with the electric light.

Both these kinds of belt are built up on a foundation of cotton or canvas, or some such fabric, and as yet I believe it has been impossible to get the rubber to enter into the body of this fabric; it simply remains as an outer coating. Unfortunately, any oil getting on the belt damages it, making the gum soft, and causing it to lose its hold on the backing. The rubber is also liable to get rolled off if a sudden stoppage either of the driving or driven pulley takes place—a short circuit of a dynamo would answer—and

Digitized by Google

thus the whole belt is quite spoiled almost in a second. The edges are also liable to get frayed, and if a cut once gets into a run in the fabric it will, unless the machinery be stopped, follow the seam the whole length of the belt. Again, these gum belts can only be used for open driving, it being simply impossible to drive them crossed.

Cotton Belts.—I shall here do little more than mention that there are such belts made, as I presume that all of you have seen them and know something about them. One of the best makes belonging to this class is the Gandy belt. The tensile strength of this belting is considerable greater than that of leather. The belt gets a better grip on the pulley than leather; in fact, Mr. Gandy told me some electrical engineers have objected to it on account of its having too good a bite, since it refused to slip over the pulley as a leather belt would when a dynamo was accidentally short-circuited. The Gandy belt will not stand a temperature of 20deg. C, but within ordinary ranges of temperature it is not injuriously affected by either damp or heat. Common yellow soap should be used to keep the inner side of the belt in a proper clammy condition.

There is another special kind of belting I should like to bring before your notice; possibly some of you know it already. I must confess that about a month ago I did not know even of its existence. This is the Leviathan belt of Messrs. Hebblethwaite, of Huddersfield. It is a combination of a woven and a leather band so combined that we have the strength of a canvas or woven belt united with the good grip of a leather belt. It is practically two belts, not a double belt, bound together by copper wire sewing and rivets. The leather only acts as a cushion, and protects the woven belt from contact with the pulley. The leather band being on the inside, comes only very slightly into tension.

Of hair belts, I have next to no information; they were, I believe, used by the Brush Company at the Manchester Exhibition with very good results. They are a comparatively new departure, and as yet have not been used extensively by electrical engineers. I have here the results of an experiment carried out by the Rossendale Company on the stretching of one of their belts (Table A.)

In mentioning the Victoria belting, in a previous part of this paper, I referred to the fact that the hair side was always next the pulley. Plain leather belts, as usually made and used, are run with the flesh side next the pulley, and there seems to be a very great difference of opinion as to which is the best way of using the belt.

I have tabulated the results of some tests which were carried out at Mr. Hoyt's factory in America. (Table B.)

The first column, "commence to slip," in Table B, refers to that point where the belt is just about commencing to slip, but has not quite slipped—it is the value of $\frac{T_2}{T_1} = \epsilon^{\mu\theta}$ where T_2 & T_1 are tensions on each side of the belt. The second column, "cease to slip," refers to the value of $\frac{T_2}{T_1}$ when the belt has a good grip of the pulley, and is the condition under which belts are usually worked. The third column, "slide," gives the value of $\frac{T_2}{T_1}$ when one surface is actually sliding over the other. A distinction is made between columns 1 and 2 owing to belts being liable to stretch, and so to diminish their tension so that they will slip.

From Table B, taking the ordinary pulley surface, it is evident that a belt with grain side to pulley gives the best results; and it is a well-known fact that by running grain side next pulley the belt will transmit nearly three per cent. more power, without slipping, than it would do if it was run flesh side to pulley with same initial strain, and running at the same velocity. For this reason some engineers say, use your belts with grain side on pulleys. On the other hand, other engineers say if you do so, your belts will have short lives, as you are not using the leather as Nature intended, and are subjecting your belt to unnecessary strains. In the table you will see other surfaces are mentioned besides polished iron, but if I went into this question at all it would make this paper altogether too long.

I have compiled in Table C the breaking strain per square inch of various different kinds of belts.

I purpose concluding this short paper by reminding you that centrifugal force plays a very important part in the calculations for finding the size of belt required when run at high velocities. In driving dynamo machines we try to run at as high speeds as possible, for the reason that the output of a given machine per unit of weight increases if the speed is increased. Now, if a belt is driven at a very high velocity owing to its not being a weightless band, the effects of centrifugal force cannot be neglected. Each portion of the belt, when passing round the pulley, is subjected to a temporary circular motion and, consequently, to a certain amount of centrifugal force, which acts always tangentially to the pulley surface, and lessens the grip which the belt would otherwise have on the pulley. To counteract this force, the initial strain we put on the belt is greater, and by doing this we reduce the useful working strain which the belt will bear.

Mr. Kapp has given the full theory of this subject, and arrives at the result that for the total strain on the belt to be a minimum, the diameter of the pulley should be such that the strain due to centrifugal force is exactly half that due to the useful work transmitted by the belt.

PHYSICAL SOCIETY.—June 23rd.

Prof. REINOLD, F.R.S. (President), in the chair.

Among others, the following communications were read:—

"Note on Continuous Current Transformers," by Prof. S. P. Thompson, D.Sc. Two classes of transformers are considered—viz., *motor-generators* and *commuting transformers*, in which a two-circuit armature is fixed in a revolving magnetic field. Such a field may be produced by using a fixed gramme ring as the field-magnet, and rotatting the brushes round its commutator. The formulæ obtained apply equally to both classes. If C_1, C_2 be the numbers of primary and secondary wires on outside of armature, E_1, E_2; c_1, c_2; i_1, i_2; r_1, r_2, the E.M.F. potential difference at terminals, currents, and resistances of primary and secondary respectively, then it is shown that $c_2 = k c_1 - (r_2 + k^2 r_1) i_2$, where $k = \frac{C_2}{C_1}$, which is called the "coefficient of transformation."

Thus, the potential difference is the same as if the dynamo part had its resistance increased by $k^2 r_1$. As the currents in the primary and secondary are in opposite directions, the effective self-induction will be very small; hence, such machines can be run with little or no sparking. In a previous paper by the same author similar properties as regards self-induction and resistance were shown to exist in alternating-current transformers. From the above equation it is evident that a motor-generator cannot be made to give constant potential when supplied at constant potential, except when the internal resistances are very small; but by over-compounding the distributing dynamo the desired result may be obtained.

Mr. Kapp agreed with the author as regards motor-generators running with little sparking; but thought the great difficulty in using them commercially would be in preserving the insulation between the circuits if anything like 2,000 volts were used in the primary. He also mentioned the method of producing a rotating field by alternating currents, recently described by Prof. Ferraris and Mr. Tesla, and thought it would be preferable to the one devised by the author of the paper.

In reply, **Dr. Thompson** said that insulation could be easily maintained between the core and windings of Brush armatures, and saw no reason why it should present very serious difficulties in continuous-current transformers.

In the absence of the author, a paper **"On the Existence of an Undulatory Movement Accompanying the Electric Spark,"** by Ernest H Cook, D.Sc., was taken as read. When sparks pass between two points placed above a plate on which some powdered substance has been scattered, the particles arrange themselves in circular lines approximately concentric with the projection of the middle line joining the two points. The proximity of the lines is found to be very nearly constant for the same powder, independent of the intensity of the spark used, or the material of the plate. Different powders give different numbers of lines per inch, and mixtures, numbers between those corresponding to their constituents. A great number of substances have been tried, giving numbers between 40 and 88 per inch. These extreme numbers were obtained for chalk and silica respectively. The author has found no satisfactory hypotheis by which to explain the results. A number of photographs accompany the paper, showing the character of the figures produced.

At the meeting an apparatus made by the late Dr. Guthrie was exhibited, with which similar figures to those described in the paper could be obtained. It consists of a shallow elliptical dish covered by a glass plate. Sparks are passed between two small knobs across one focus, and powder, sprinkled on the bottom, forms into circles about the other focus.

THE
ELECTRICAL ENGINEER.

Published every Friday.
Price Threepence; Post Free, Threepence Halfpenny.
Editorial and Publishing Offices:
139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months.	6 months.	12 months.
United Kingdom.....	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places.....	4s. 10d.	9s. 8d.	19s 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, ESQ., *President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of* W. H. WOLLASTON, M.D., F.R.S., *and on April 20th we gave that of* SIR HUMPHRY DAVY, F.R.S., *whose fame as an electrician is still more prominent than that of* WOLLASTON. *Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of* PROF. D. E. HUGHES, F.R.S.

FOREIGN COMPETITION.

Travellers all agree that wherever they go, and whatever enquiries they make, one fashion is persistent throughout the whole world, and that is to decry home-made materials. Shopkeepers display foreign goods in their windows, and pretend their whole stock is imported. There is a weakness among poor humanity to dabble in business with anybody whose mother tongue is different to our own. The foreigner, be he Frenchman, German, Italian, American, or Heathen Chinee, gravitates towards England with his notions, proceeds to obtain provisional protection for his ideas, and sell them to the Briton. On the other hand, the Briton seems quite as eager to tempt fate and lose his money, as the foreigner is to get the money; for if the latter does not come here, the Englishmen sends to the four quarters of the globe gathering in, and paying for, all the "notions" that come in his way. It would be an easy task to make up a small directory giving the names and addresses of men in England, though neither Englishmen by birth or naturalisation, who manage to live as gentlemen, and amass considerable fortunes, simply by preying upon the gullibility of the many possessing a little money, and desirous of increasing their store at a far more rapid rate than is compatible with safety. These gentlemen exploit patents, pull the strings that make the political press to dance, organise syndicates, promote companies, and clear out with a nice little haul when allotment is made. Occasionally, their efforts lead to the launching of a good thing at an enormously increased cost, but their one success is the red flag that makes John Bull rush to the charge, whenever it is waved, ever after. No sympathy is due to those who contribute to the funds of these smooth-tongued promoters. They willingly take the bait, and gleefully pit their brains against those of the angler. If they lose, they lose with their eyes wide open, and certainly the money passes into the hands of those better able to look after number one than was the original possessor. The only regret is that a certain amount of capital that might have been expended usefully is probably lost to the country. The case is but another example of the Greek spoiling the Turk. There is another phase of competition which probably hits our own business men, whether they be manufacturers or distributors, harder than any other. Take any piece of apparatus—electrical or otherwise—made in large quantities in England, and equally well, say, in America. Our own business men complain, and complain justly, that there exists a class of men who accept pay from the foreigner, cry up his wares to an admiring public, and pave the way for him to gain a good footing in the English market. It is exceedingly difficult to specialise any case, but no doubt every reader will be able to find an example for himself.

Digitized by Google

In many cases no doubt our manufacturers have to thank their own supineness, and nothing else, for competition that threatens their extinction. Let us take one simple example. Almost everybody wears a watch, and electricians have to undergo the troubles attendant upon their watch becoming magnetised. American watchmakers provided against this, and produced watches which are uninjured by proximity to large dynamos. They are always directing attention to these manufactures, but, with perhaps one or two exceptions, and these at rare intervals, what English watchmaker troubles himself upon the question? Because he is unable to gain the ear of the profession and induce orders at once, the Englishman is content quietly to drop behind in the race, and allow his rival a field in which to work at his leisure. The one case we have referred to is among the least important directions of competition. We have called attention to this phase of business because there seems to be a tendency in some quarters to ignore our own manufacturers in the case of all that pertains to the transmission of power, and strong efforts are being made to bring in systems connected with tram work which, if not altogether unsuitable, are not so good as can be had at home. It is certain that neither with overhead, underground, or accumulator systems is there anything abroad that is superior to what is well known at home. This fashionable craze for imported goods has led to great loss of time and money, and is likely to lead to greater losses; but so far as electrical work is concerned, we really ought to be raised above that sphere of ignorance that leads to those mistakes, and be sufficiently acquainted with the work to trust the ability and knowledge of our own engineers.

TELEPHONY.

According to the report of the United Telephone Company's meeting, an abstract of which is given elsewhere, the shareholders are becoming inconveniently clamorous for certain information. They are beginning to realise that the most profitable position in the company is that of a director, and that, while the directors are paid to the tune of nearly £10,000 a-year, the shareholders are looking forward, not to the continuation of good dividends, but to the possibility of their company being swept away by the action of the Government. The answer of the directors to the criticisms of the shareholders was practically this: "You are not behind the scenes—we are; and being so, know our policy to be the correct one, and that which you advocate a dangerous one." This answer upon the face of it is a good one, and, to a certain extent, unanswerable. No doubt the policy of the directors has led to a good dividend, and has increased the value of the shares till they stand at a very high premium; but the shareholders evidently feel an insecurity of tenure in the future, and it is this inability to see what may happen that is creating alarm. In reply to the remarks about call offices and the increase of such offices elsewhere, the directors stated that the principal returns were from the exchanges; that they desired to interfere as little as possible with the exchange or with their constant subscribers. There was, however, little notice taken of the accusation that the subscription was too high, and that it would be far better to lower the tariff to induce every householder to be upon the exchange rather than continue the exclusive rates as now imposed. We quite agree that the management of the Telephone Company is not what it should be, and that the shareholders have great cause for feeling insecure. With regard to the consideration of subscribers, the management might take a leaf out of the history of railway management. From the time that the comfort of the passengers was more carefully considered, the rise in value of railway securities has continuously increased. Those lines that cater least for comfort are those that are patronised the least. We contend that the criticism of the shareholders is both just and logical, and that the revenue of the company would be increased by leaps and bounds if the requirements of business and home life were more considered. If the statement is correct that at certain periods of the day the exchange work is almost more than can be managed, it speaks volumes for the incapacity of the management. There should be a very large margin for development, and no trunk line and no system of lines should be erected without due provision being made for such development. More than once we have ventured to differ about the management of the company, and it is highly satisfactory to find the shareholders awakening to their position.

CORRESPONDENCE.

THE BRITISH ASSOCIATION OF MEDICAL ELECTRICIANS.

To the Editor of The Electrical Engineer.

Sir,—My attention has been drawn to your note headed "Medical Electricity," which appeared in last week's issue of *The Electrical Engineer*, on page 601, Vol. I.

I am pleased to notice you mention the fact that "The British Association of Medical Electricians" is in no way connected with "The Institute of Medical Electricity, *Limited*"; but the other statements contained in the paragraph referred to are entirely incorrect and misleading. You have evidently been misinformed either by a person or persons having a pecuniary interest in "The Institute of Medical Electricity, *Limited*," or by some of the Medical Battery Company's discharged servants, who, out of spite and jealousy, wish to try and damage our association because Mr. C. B. Harness, their late employer, has been elected president.

I am surprised that your paper should lend itself to such petty manœuvres. Surely, in justice to our association, you should have obtained authentic information on the subject before making such grossly inaccurate statements.

The British Association of Medical Electricians is *not* formed for commercial purposes, as you state, and none of

Digitized by Google

its members can receive any portion of its funds. I enclose herewith a circular, from which you will see that our association is formed purely for the investigation and development of medical electricity, and all the funds of the association will be devoted to that purpose. The "Institute of Medical Electricity," on the contrary, is a *limited* company, formed purely for commercial trading as a financial speculation, although the public have, to some extent, been misled by the *eminent* "A.S.T.E.," Mr. H. Newman, Lawrence, writing letters to the press, and carefully omitting the word "limited" after the name of the company, contrary to the Limited Liability Act.

I hope you will be good enough to insert this letter in your next issue, so that the few facts I have stated may be known to your readers.—Yours, &c.,

H. C. SHARMAN, Secretary.

39, Hatton-garden, London, E.C.,
July 3, 1888.

The following extract from the articles of association has been sent with the above letter:

"The objects for which the association is formed are to promote and encourage the study and practice of medical electricity, for which purpose facilities will be afforded for the reading of papers, the delivery of lectures, the prosecution of experimental research, and the free interchange and publication of ideas and experiences of those who are engaged in the study or practice of medical electricity, and in the investigation of allied sciences. To encourage those who recognise the claims of these questions to their serious consideration, as well for their scientific interest, as for their practical importance as a department of the healing art. To maintain the honour and interests of the medical electrical profession by the aid of all or any of the following:—

"(*a*) Periodical meetings of the members of the association and of scientific men and others interested in the study of medical electricity;

"(*b*) By the publication of such information as may be thought desirable in the form of a circular or journal, or by reports to be published in existing independent periodicals;

"(*c*) By the occasional publication of transactions or other papers;

"(*d*) By the grant of sums of money out of the funds of the association for the promotion of the medical, electrical, and allied sciences in such manner as may from time to time be determined on;

"(*e*) And such other lawful things as are incidental or conducive to the attainment of the above objects."

THE ELECTRIC LIGHTING ACT.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—We beg to enclose you copy of letter addressed by Lord Thurlow to the members of the executive committee of the Electric Lighting Act.—Yours, &c.,

ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION, LIMITED.

Belvedere-road, Lambeth, S.E., July 3rd, 1888.

Sir,—In thanking you for the valuable support and assistance you have extended to me as Chairman of the Electric Lighting Act Committee, without which support it would have been useless for me to have attempted to move in the matter, it affords me great pleasure to inform you that the Bill amending the Act of 1882, framed on the lines recommended by your committee, and introduced by me into the House of Lords this year, has now passed both Houses of Parliament without material modification, and only awaits the Royal assent to become law.

Under this Bill, 42 years are substituted for 21 as the life of a provisional order, and 10 years for seven for that of a license; more favourable conditions are also prescribed in the event of compulsory purchase by a local authority at the end of the term.

I sincerely hope that this successful termination of our efforts during the last three years may render it possible to attract the necessary capital to enable the electric lighting industry to advance without further delay on its career of utility, beauty and economy.

My own opinion is, that with the alterations in the Act now effected, and with good management, no reason exists why electric light undertakings should not now prove commercially and financially successful, and become a well recognised investment for capital at least as profitable as gas shares, or other equally popular securities.

With reference to our committee I should propose that it be not dissolved, but continued in existence, so that it may from time to time be called together for deliberation and consultation as occasion may require. On this point I shall be glad to have the benefit of your opinion.—Yours, &c.,

THURLOW.

26th June, 1888.

DISCLAIMER.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—In the list of patents in the current issue of your journal you cite the Patent Application No. 8,920[88] as if I were the inventor. Kindly note that the name of the Société d'Exploitation des Câbles Electriques should appear in this, as in the immediately preceding application. My position in the matter is simply that of patent agent, not inventor.—Yours, &c.,

J. G. LORRAIN.

Norfolk House, Norfolk-street, Strand,
London, W.C., July 4, 1888.

[It will be found that the Official Journal does not always give such details as are furnished by our correspondent. Thus, Specification No. 9,264—referred to in our list this week—is given in the Official Journal as of Mr. J. G. Lorrain.—ED. *E. E.*]

MR. J. W. SWAN'S GARDEN PARTY.

A garden party was held in the grounds of Mr. J. W. Swan, M.A., at Lauriston, Bromley, Kent, yesterday afternoon, at which a large number of scientific men and a large proportion of ladies were present. *Réunions* of this kind are exceptionally interesting from the fact that many of the most recent applications, especially of electrical science, which to ordinary persons are matters of scientific interest only, or at most of knowledge only through rumour, hearsay, or description, are here seen in actual presence. No small pains had been taken to have some of the latest novelties in electric science, which we shall presently describe, as well as—for the ladies—those of social interest, in the shapes of the renowned American whistling lady and other musical delectations.

Mr. Swan's house, as our readers are probably aware, is itself very beautifully fitted throughout with the incandescent electric light, and constitutes a sight of very considerable interest and beauty. The living rooms are fitted with daintily-tinted electroliers, supplied by a dynamo, gas-engine, and accumulators in an outhouse near. The grounds are lighted with large incandescent lamps of 500 c.p., making the whole garden at night clearer than moonlight.

THE ENGINE-ROOM

was thrown open, and was the centre of a great deal of interest. The dynamo is a unique type, of Mr. Swan's own design, probably as perfect a machine as it is possible to make. Its field-magnet is one huge ring of soft iron, on which flattened rings of insulated copper tape are separately slipped, soldered together on connection at the top. This arrangement allows radial spaces round the outside of the field-magnet, which by this means remains probably cooler than any other type of machine. In the engine-room a small motor was arranged, lent for the occasion by Messrs. Immisch and Company, which, mounted on a pedestal, was made to drive the lathe in the laboratory adjoining, the current being obtained from the battery of accumulator cells. The running of this powerful, but diminutive, motor excited a good deal of interest; an explanation was appended, indicating how mechanical motion was obtained by the continual chasing round and round by the poles after magnets which they could never catch.

PROF. ELIHU THOMSON'S METHOD OF ELECTRIC WELDING.

The attention of engineers and electricians has been directed during the past few months to the system of

Digitized by Google

electric welding invented by Prof. Elihu Thomson, of Lynn, U.S.A., and at present most successfully worked in the States by a Boston company. One of the most noticeable features was a specimen apparatus of this welding process, which was lent for the occasion by the agents of the Thomson-Houston Company in England—Messrs. Laing, Wharton and Down—previous to its instalment at the Italian Exhibition. The alternating dynamo which supplies the current for the transformer (the whole being on one stand) was driven by a portable steam-engine fixed in the garden. The principal feature of Prof. Thomson's apparatus is the large coil of fine wire surrounding one single coil of very thick copper, by means of which arrangement a comparatively small current at a high pressure is transformed into an enormously large current at a low pressure. A popular description of this welding apparatus was appended for all to read, giving a general idea of how the heating effect of a large current was used to fuse the metals, which are pressed together by the action of the apparatus; the certainly interesting statement was thereon made, that for the short period of a second or two during the making of a large weld, the current required is equal to that carried by 10,000 ordinary incandescent lamps, though the pressure used was only $\frac{1}{100}$th of that ordinarily used for lighting.

Without going deeply into details of the theory of the process, the scientific principle involved and practical method of working the electric welding apparatus may be briefly described as follows:

An electric current flowing through a circuit generates heat at every portion, and the higher the resistance of any part of the circuit, the more the heat generated at that part. Therefore, if an electric circuit of otherwise almost inappreciable resistance be completed by the slight contact formed by the abutment of the pieces to be welded, upon the passage of a sufficient current through the circuit this point of contact may be speedily brought to a welding heat, and, by a suitable pressure, may be firmly united when at this heat. In practice, the pieces to be operated upon are tightly held by clamps, which hold the pieces in correct relative position, and may also serve to conduct the current into the pieces. Both the current and pressure can be delicately regulated, with the result that all pure metals, most alloys, and many combinations of dissimilar metals, can be united.

The value of the process will be easily seen, since it is possible, without the aid of the forge fire, and with a minimum of time, labour, and expense, to form perfect welds between almost all sizes and shapes of metals. The system of electric heating is also free from the impurities of the ordinary forge, and the heat is easily localised at any desired point. This is important in the welding of high grades of steel, since the metal is not impaired, nor is the "temper" withdrawn, except directly at the weld. The same source of heat may be employed for retempering or annealing by any of the ordinary processes.

The applications of the process in practical work are almost limitless, but the following rough classification will present some of the more important uses:—

(*a*) The joining of wires for cables, electrical work, and other purposes.

(*b*) The joining of solid bars and rods of all shapes. This would be important in bridge work, in the formation of long lines of shafting and rails, in working angle iron and the making of "T" and "Y" joints, in the shortening or lengthening of tools, rods, &c., for particular purposes; in the making of tools where a hard steel, employed for the cutting edge, could readily be joined to a milder steel or iron; in all sorts of general repair and construction work.

(*c*) Chain and link work: Making links of all shapes and sizes. Employing steel in place of iron for chains, and thus obtaining a chain of maximum strength for a minimum of weight; also in the formation of ornamental chains of any precious metal or combination of metals.

(*d*) Pipe work: The forming of continuous lines of piping without screwed joints; also in plumbers' work. The longitudinal welds of large piping and boiler flues could be readily welded by the electric process.

(*e*) The welding of rings, hoops, and tins would offer a large field for the process. Welds could be effected in those places where the ordinary method would prove too coarse, and where riveting and brazing are now substituted for welding.

(*f*) The local heating of metals for tempering, annealing, bending, shaping, &c.; also for raising solid collars upon shafts, axles, &c. A most important application will be had in the heating and heading of bolts and rivets at a single operation.

(*g*) The substitution of the electric heat for brazing and soldering in place of the blowpipe, as being more speedy and economical than the latter method.

While this process is particularly fitted for special work, a welding apparatus with adjustable clamps for holding all shapes of material would be invaluable for general use in the workshop.

Numerous tests have proved that the weld in all cases is most satisfactory, and generally of equal strength with the original solid metal.

The cost of welding by this process is much less than that of the ordinary forge-fire method, nor is a knowledge of electrical laws nor skilled labour required. The working of the welding machine is absolutely without danger to the operator.

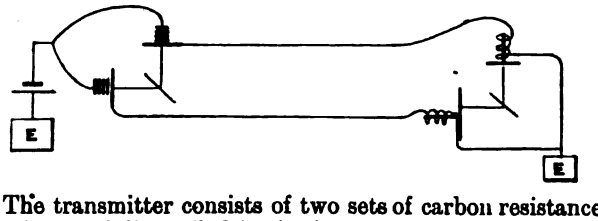
The above-mentioned applications give but slight idea of the vast fields for the process, and new uses may be found in nearly every workshop.

It may not be unreasonable to suppose that in time the largest shafts, boiler-plates, &c., will be united by this electric method, and that the new invention will grow in utility and general use as has the electric telegraph, and more recently the telephone and electric light.

Numerous specimens of welding on different metals from $\frac{1}{16}$th to 1in. thick were shown.

Robertson's Writing Telegraph.

Another point of universal interest was the writing telegraph, which was worked and explained by Mr. Johnson Stephens, who is acting as agent in England for the Writing Telegraph Company, of 46, Holborn-viaduct, who kindly lent the instruments for the occasion. This instrument reproduces the actual handwriting of the person sending the telegram, and is expected to be largely used instead of, or in conjunction with, the telephone for general uses, and especially for messages which require documentary evidence. The principle of the writing telegraph is dependent upon the possibility of analysis of the motion of writing into two separate motions—one an up-and-down motion, and the other a backward-and-forward one. These motions which are combined in the various curves in the act of writing, are separated into the two motions by the movement of a stylus acting upon two arms at right angles in the instrument, which are made to send two currents of varying intensity through the wires, producing separate movements at the further end, which are reunited, thus reproducing the facsimile of the original curves. The credit of the first application of this analysis into two motions and their subsequent synthesis at the further end has been given to Mr. Cowper, in England, but in his apparatus separate resistances were used which, varied by the action of the stylus, produced a number of step-like motions which approximated to curves. The action was of course disjointed in the same manner that Reis's telephone was, and the method that was independently invented and brought to perfection by Mr. J. Hart Robertson, in America, differs in exactly the same manner from Cowper's as Bell's telephone does from Reis's. Indeed, the whole action of the writing telegraph can best be studied from the point of view of the telephone, and can be readily understood from the accompanying diagram:—



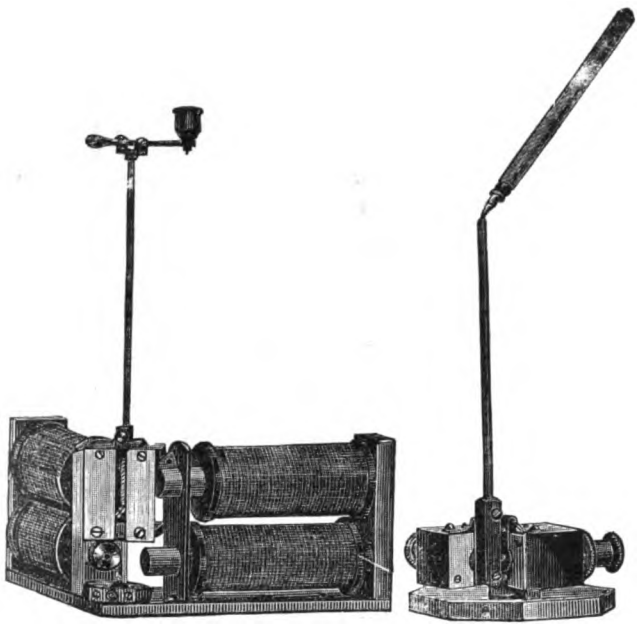
The transmitter consists of two sets of carbon resistances, consisting of discs piled in the form of a rouleau, like coins, in small boxes, and fixed at right angles to each other. Let it be granted that, in the manner of the telephone, any

Digitized by Google

vibration on the tympanum of one of these boxes, by varying the resistance of the carbon discs, alters gradually the strength of an electric current passing through them, and, by acting upon a magnet at the further receiving end, reproduces the vibration produced at the transmitter. The

Specimen of writing.

same effect is produced in the second set of resistances and receivers. If the two motions are combined by an action pulling upon the membranes at the same time, the result upon the two receivers likewise combined will be a series of lines, curved or straight, according to the pull of the levers. Any curve that is made, therefore, at the transmitting end, will be resolved into its constituent movements by the arms of the two membranes, and can be made to transmit distinct and varying currents along the lines. These can be received by the two magnets acting upon similar membranes at the further end, and recombined into the original curves by the stylus. This is, in effect, the action of the writing telegraph. The parts of the writing telegraph are shown in the accompanying illustrations. The transmitter consists of a pencil or stylus fastened to the long lever arm by a ball and socket joint to allow of motion in any direction, and to accommodate itself to the hand. This lever projects slightly through the box. Motions are made with the stylus as if in writing letters, which cause pressure of more or less degree to be made on the carbon resistances below, and varies the current in the lines in like degree.

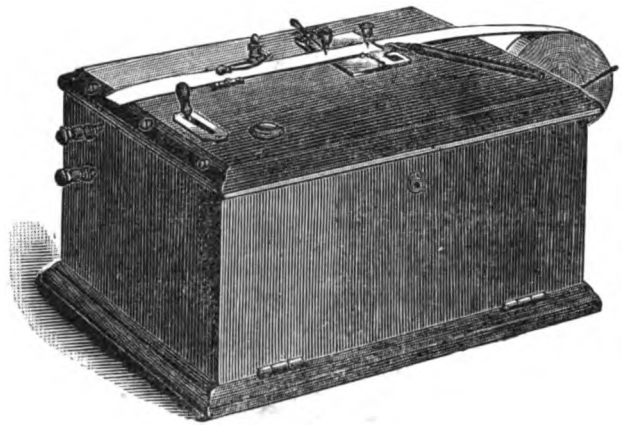


Receiver. Writing Telegraph Transmitter.

Of course, as this stylus is fixed to the lever, the motion cannot be extended far to the right as is usual in writing; the writing is done as if one were writing in the air. The receiver of the same instrument is in circuit, however, and the strip of paper, as it passes along from left to right, reproduces the motion of the writer, who can thus see before him what he has written.

At the other end of the line the currents are received by two electro-magnets placed at right angles; these act upon an armature pivoted at one point, and having a long lever arm carrying a fountain pen. The combined action of the two electro-magnets upon the armature reproduces the motion of the stylus from the other end. The appearance of the instrument exhibited is seen in the cut.

It was at first thought necessary to use two batteries, one for each transmitter, but it has been found by Mr. Stephens to need only one, and, in fact, to work better with one than two. The number of carbon discs employed is usually about twenty; the resistance can be easily varied by these from 2 to 200 ohms. The usual instruments are made to work on a double five mile circuit, which would be about right for ordinary exchanges—that is, five miles from each instrument to the exchange. For exchange use it is not necessary to have separate batteries; all the battery power would be at the central station. A switch is provided to put it into condition for either receiving or transmitting, and this is usually left at "Receive." On moving it, a small Leclanché battery at the central would put it into circuit; the number required can be transmitted to the attendant at the central, who then by a current starts the other person's receiver, and the message can be received even if



The Writing Telegraph.

no one is there, which is not, of course, the case with the telephone. A rough clock movement released by a detent works the paper-carrier. The message can be run off automatically into a locked receptacle to await the owner's return.

As the alternations of current are very gradual compared with those of the telephone, the writing telegraph can be duplexed upon the telephone wires without in any way interfering with the speaking qualities of the telephone. As the messages are in exact fac-simile of the original writing, and are, in fact, as much the original writing as that in the writer's own office, they can be accepted as proper documentary evidence, and for this purpose will have equal value with ordinary letters. For the transmission of club and Stock Exchange news it would prove most useful and simple. The receivers, arranged in series, could all be actuated by one transmitter, and the parts needed for each receiver would be simply the two magnets and lever arm with pen, and the clockwork movement, which all could be set in motion from the one office.

Several small improvements have been made in the action of the pen since first exhibited, and the method of application in exchange use more fully developed.

Pollak's Arc Lamps.

A simple arc lamp, actuated by the variations in length of a wire heated by the current, was exhibited. This lamp

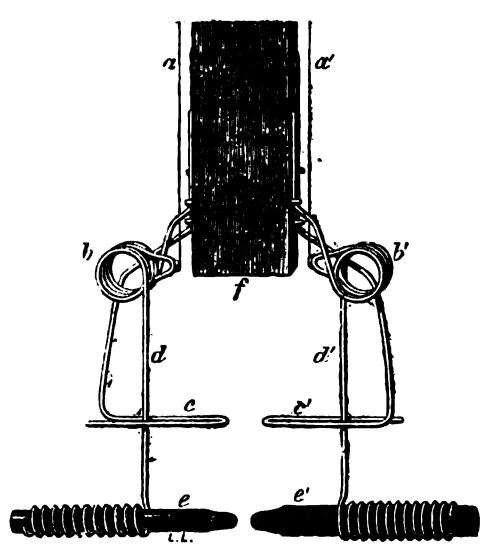


Fig. 1.

is known as the Pollak lamp. Fig. 1 shows the first apparatus of the kind, and will easily be understood from the illustration: $a\ a^1$ are brass wires, from ·4 to ·5mm. diameter,

Digitized by Google

intended to carry a current of 5 amperes. One end of the wire is fixed to the spirals, b b^1, which are continued in the straight pieces, d d^1, which again take the spiral form, acting as carbon-holders, e e^1. The expansion and contraction of the wires, a a^1, acting at the end of a lever, as shown, increases or decreases the length of the arc. In Fig. 2 the wires, a a^1, similarly act at the ends of levers

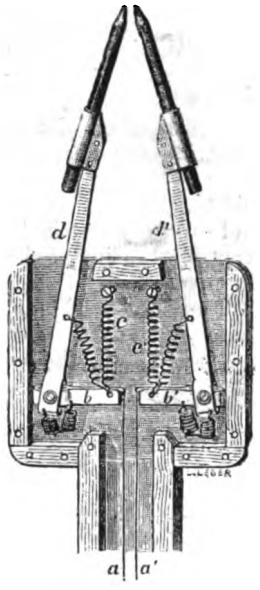

FIG. 2.

and against the action of springs, as shown. The form of lamp exhibited was the simpler one, the most recent is a much more elaborate affair.

RAUB'S THERMO-BATTERY.

One of Raub's new thermo-batteries, of which we have given some description in preceding numbers, was fixed in the laboratory in place of the gas stove removed. The battery has much the appearance of an ordinary stove on a bracket, and is heated from below with Bunsen burners, part of the heat being converted into electricity, and the remainder serving to heat the room. The second or middle size of thermo-battery was shown, giving a current of 20 amperes, when the external resistance is equal to the internal, and having an E.M.F. on open circuit of 3 volts. The internal resistance of the battery is 0·06 ohm. The novelty of this battery consists in the application of ring-shaped elements, made a hollow core for the flame, instead of alternate blocks and strips as in earlier forms, together with the employment of the heated air to draw up cool air round the outer terminals of the thermopile. The elements are made of a zinc-antimony alloy, and of German silver alternately. Mr. Swan had sent over to Berlin for a specimen of this thermo-pile specially for the occasion, as the greatest advance in this department, and shown as interesting on account of the strength of current obtained, which is considerably in excess of any hitherto produced by means of gas burners. Mr. Swan looks forward to some such combination of heating apparatus and electric thermopile for charging accumulators for the house lighting, as possibly "not only useful, but even economical."

An earlier form of thermo-battery—that of Noë—was also shown, in conjunction with a small incandescent electric lamp. This battery has three large gas-burners, and the current produced lighted the lamp, which was mounted on a stand and connected to the battery by a flexible wire, and gave, when fully in action, about 5 c.p. It was interesting to note the continued action of the thermopile for some considerable time at full power after the gas has been turned off by the utilisation of the heat already given, a kind of kinetic energy effect in the heated particles of the pile.

MINERS' LAMPS.

The specimens of Mr. Swan's latest types of miners' electric lamps were examined with much interest. These consist of a set of small storage cells, in conjunction with a special small incandescent lamp inserted under a bullseye. The lamp itself is out of all contact with the air, and cannot cause an explosion. It is thus a true safety lamp.

PROF. LODGE'S DUST SETTLER.

A small piece of apparatus was exhibited in connection with a Wimshurst influence machine, which has excited a great deal of attention. This was Dr. Oliver Lodge's dust settler. In the small experimental primitive form shown it consists of a glass receiver, having two rows of brass spikes arranged inside and opposite each other. Below is a compartment where brown paper or magnesium wire can be burnt to generate a thick smoke, which fills the whole glass receiver. On turning the handle of the Wimshurst machine the dust particles rapidly settle, leaving the air quite clear, by the electrification of the smoke particles.

This method of causing dust to settle, exhibited first in this small form, has already had its practical application in mills, where dust abounds, and it has been found useful in the ordnance departments, where the dense smoke after firing heavy cannon in a confined compartment, which often renders everything invisible for many minutes, can be settled by a few turns of an induction machine. It might certainly, it is suggested, be worth the while of the great Mr. Augustus Harris to introduce several of these machines into the Drury Lane Theatre before next November, so that inside, at least, the air might be made clear by the silent discharge of electrified points, even while outside all London suffered from a "pea-soup" fog.

THE PARTY.

The weather, always a momentous point in an English garden party, had been anxiously watched for days previously, fearful lest the occasional storms and downpours should put a damper upon the festivities. A severe downfall came on in the morning, and throughout the weather was very variable, but the gathering was extremely enjoyable. The sombre and scientific unbent in inspecting the many practical equipments provided for their interest, and in explaining and showing forth the wonders of electricity to the fair visitors, who wondered when the result of all these applications should likewise be brought to their own doors.

A STUDY OF CERTAIN ERRORS IN THE CONSTANT SHUNT METHOD.*

BY WILLIAM L. PUFFER, S.B.

A very neat and valuable application of Ohm's law is that usually called the shunt method for the determination of current. The method is described in the Munich, Vienna, and Philadelphia reports on dynamo tests, as well as in the *Electrician* and *Electrical Engineer* for January, 1885.

The principle is this: If a conductor of constant unknown resistance be placed in a circuit, and currents of different strength passed through it, there will be a difference of potential at the terminals of the conductor proportional to the currents flowing; and if this conductor be placed as a shunt upon a reflecting galvanometer whose resistance is high as compared to the conductor, and whose deflections are proportional to currents producing them, then the deflections will be proportional; first, to the currents in the galvanometer circuit; second, to the potential difference in the conductor: and, third, to the currents in the conductor.

In order to extend the range of the apparatus, the galvanometer deflection can be kept the same by changing the total resistance in its circuit; then this total resistance is also proportional to the potential difference in the conductor. In order to save time, the galvanometer deflection may be nearly the same, and the product of the deflection and corresponding total resistance taken; these products will then be a measure of the corresponding currents in the conductor. If a known current be passed through this conductor or shunt, and the galvanometer deflection and total resistance of the galvanometer circuit multiplied, and the product divided by the known current expressed in amperes, we get the constant of the apparatus for amperes. To find value in amperes of

* Read at the meeting of the American Academy of Arts and Sciences January 11, 1888.

Digitized by Google

an unknown current, we have only to note the deflection and total resistance in galvanometer circuit, multiply them, and divide by the constant. Or we could divide the known current by the product of resistance and deflection, and get a constant by which to multiply the resistance and deflection obtained with the unknown currents.

The range of the method is very great, and is, perhaps, limited only by the difficulty of making a suitable shunt of such a cross section as to be free from injurious heating by the currents used.

Wishing to employ this method in the Roger's Laboratory of Physics in a slightly different way, requiring that the shunt resistance be known, I made some experiments to determine the resistance of a German silver rod, 3ft. long and 0·6in. in diameter, with the intention of using it as a constant shunt of *known* resistance for currents from about 1 to 60 amperes. An inch from each end a small wire of German silver was silver-soldered in a hole drilled nearly through the rod, and the lead wires running to a low resistance galvanometer were connected by screw-clamps. On the ends of the shunt were soldered brass screw connection for insertion of the main wires.

A standard ohm was placed in circuit with the shunt by means of mercury cups, and the resistance of the shunt found by comparison of the potential at its terminals with that at the terminals of the ohm, using a Hartmann dead-beat galvanometer and resistance box as usual with the shunt method.

The results were very unsatisfactory, although care had been taken to prevent, as far as possible, any error due to change in temperature, by placing both the shunt and the standard ohm in a water bath, and noting the temperatnre both before and after a set of readings.

As the observations were taken in a short time, and the resistances measured immediately afterwards, it is not probable that there could have been any noticeable change during the experiment.

With the shunt in water, the results checked within about 0·3 per cent., the highest being 0·00 085 39, and the lowest 0·00 085 10 ohm. When the shunt was in melting ice the results were more variable, and in air very bad. A careful test of the wires and connection showed that when there was no battery in circuit there was a variable E.M.F. in both the galvanometer circuit and in the shunt itself sufficiently great to account for the errors in previous work.

The error in the galvanometer circuit was avoided by greater care in manipulation and the use of a mercury commutator; but the shunt proved so troublesome that a study of the nature of the small, disturbing E.M.F. force observed seemed desirable.

As this error, which I attributed to thermal action, was entirely negligible in the standard ohm because of the comparatively high difference of potential produced by the calibrating current, I thought that a German silver shunt, capable of carrying 5 to 10 amperes, having a resistance of from 0·1 to 0·2 ohm, might be compared with the ohm, and then with the shunt, without any appreciable error from heating or thermal action.

The following is a brief description of the shunts made, and the arrangements for taking observations and avoiding errors:—

The large German silver shunt has already been described. The standing German silver shunt was made of a 50ft. length of wire of ¼in. diameter, drawn to order, and of the quality known as "18 per cent." A short length of No. 14 German silver wire was looped around this shunt near each end and silver-soldered to it, using borax as a flux, and similarly a set of copper wires as well, thus giving me virtually two shunts of the same resistance and material, differing only in the metal wires used for the potential leads. The shunt wire was doubled and bent back and forth through porcelain insulators fastened to a piece of board. Also, a copper shunt was made of two pieces of No. 00 wire, each 11ft. long. These were connected by being soft-soldered into a brass block, using resin as a flux, and then coiled in the same directions, to avoid magnetic disturbance, and suspended from ebonite supports in a stone jar. At three places on this shunt—near each end, and in the middle near the brass block—were soldered a set of four wires. Each set of four contained a German silver and a copper wire, silver-soldered with borax, and a similar pair soft-soldered with resin. This was equivalent to twelve simple copper shunts, with different leading wires and solders.

Each of these three shunts was placed in a tank of water provided with a thermometer. The potential wires were carried to mercury cups and commutators on a table thirty feet away, where the resistance boxes were placed.

The galvanometer was a double-coil Hartmann, with bell magnet and copper damping-block; the deflections were read by a telescope and scale at a distance of 3·68 metres.

The galvanometer wires were soldered to amalgamated brass rods, held in a piece of ebonite provided with a long handle, used in changing the connection from one set of wires to another.

In order to avoid temperature correction, the shunts were placed in water and carefully watched until it was evident there was no perceptible heating of the water or wires by the current. A loop of the galvanometer leads was always connected to a Wheatstone bridge used to measure the resistance in circuit. There was never any change large enough to cause any trouble, as the measurements were all taken in a short time, and the rise of temperature was very slow.

The deflections were always brought to about 10 double centimetres each side of the middle of the scale, and were written 1,000, calling the tenth of smallest division unity. Within the limits of the scale the proportionality of the deflections was nearly perfect, and quite so within the limits of working. The error due to change in length of the suspending fibre was studied, and found to be negligible only when the precaution was taken to compare a mark on the mirror with a mark on the metal frame of the instrument, and adjust the height of the mirror to 0·1 or 0·2 millimetre. The torsion of the fibre was negligible in the range of deflections used.

The galvanometer and its connecting wires had a resistance of 4·7 ohms, and was used as a voltmeter for measuring the thermal E.M.F.'s with an accuracy of about 5 per cent. The factor 0·00 000 040 was used to multiply the deflections by in order to obtain the thermal action in volts, when no resistance other than the galvanometer and connecting wires was in circuit.

It was assumed that these shunts would be calibrated with a current of 1 ampere, and that an accuracy of 1 part in 1,000 was desirable. The table gives the resistance of the shunts, and also the volts corresponding to an error of 0·1 per cent. of the difference of potential caused by a calibrating current of 1 ampere. These small E.M.F.'s are represented by two units of deflection of the voltmeter in the case of the copper and the large German silver shunts, and 2,000 with the standard shunt.

	Resistance in ohms.	0·1% P.D., due to an ampere.
Large German silver shunt	0·00 085	0·00 000 085
Standard German silver shunt.....	0·16	0·00 016
Half of copper shunt.....	0 00 070	0·00 000 070

The large G. S. shunt in air often showed from 1 to 3 units deflection, sometimes in one direction and sometimes in the other; but when placed in water this error was reduced to a much smaller amount, and seldom could be detected. At one time there seemed to be a variable deflection, which was traced to the contacts in the screw connection used to join the galvanometer leads to the shunt wires. This was easily removed by bending the wires until the clamps were under water. After this I could never detect any deflection caused by thermal action in this shunt, although owing to the low resistance of the shunt an error of 0·05 per cent. would cause so small a deflection that it might pass unnoticed.

The copper shunt, with its different terminals, proved very interesting, and exhibited a great variety of thermal action which would in many cases be too large to be neglected if the shunt was to be used for comparison of currents.

(To be concluded.)

LEGAL INTELLIGENCE.

SWABY v. WATT AND OTHERS.

In the High Court of Justice, Chancery Division, on the 29th ult., before Mr. Justice Stirling, the case of Swaby *v.* Watt and others was disposed of.

The plaintiff in this case was a director of the Maxim-Weston Electric Company, and he moved the Court that the defendants might be restrained—(1) from forfeiting or cancelling 400 shares in the capital of the Company held by him; (2) from allowing any notice, minute, or entry alleging such forfeiture or cancellation to remain on the register or in the minute-book of the Company; (3) that the defendant Howell might be restrained from acting as a director of the Company; and (4) that the defendants might be restrained from excluding the plaintiff from meetings and from interfering in any way with his acting as a director of the Company. The defendant, Mr. Hugh Watt, M.P., was the chairman of the Company, and the defendant, Mr. George Howell, M.P., claimed to have been duly appointed a director. The facts of the case appear sufficiently from the judgment.

Mr. W. Pearson, Q.C., and Mr. Gazdar appeared for the plaintiff; Mr. Graham Hastings, Q.C., and Mr. Alexander Young for the defendant Howell; and Mr. Buckley, Q.C., and Mr. Robert Wallace for the Company.

Mr. Justice Stirling, in giving judgment, said:—"The evidence adduced in this case shows that some very singular transactions have occurred in this Company. In the first place, the plaintiff, who is a director of the Company, asks to be relieved from an alleged forfeiture of his shares, and that alleged forfeiture is certainly the most curious that I ever heard of. It is provided by Article 23 of the Company's articles of association that—'If any member fails to pay all or any part of any call or instalment on or before the day appointed for the payment of the same, the Directors may at any time thereafter, during such time as the call or instalment remains unpaid, serve a notice on him requiring him to pay the same, together with any interest and any expenses that may have accrued or been incurred by reason of such non-payment. The notice shall name a further day (not less than 14 days from the date of the notice) and place or places on and at which such call and instalment and all interest and expenses that have accrued or been incurred by reason of such non-payment are to be paid. It shall also state that, in the event of non-payment at or before the time and at the place appointed, the shares in respect of which such call was made or instalment is payable will be liable to be forfeited." And Article 24 provides that—"If the requisitions of any such notice as aforesaid are not complied with, any shares in respect of which such notice has been given may at any time thereafter, before payment of all calls or instalments, interest, and expenses due in respect thereof, be forfeited by a resolution of the Directors to that effect."

It appears that disputes having occurred between Mr. Watt and Mr. Swaby on March 19, 1888, the solicitors of the Company wrote the following letter to Mr. Swaby:—"We are instructed by the Maxim-Weston Electric Company, Limited, to apply to you for payment of 5s. per share on the 2,000 shares which on your application were allotted to you in October, 1886. And we have to acquaint you that unless the amount be paid to us, together with interest at 10 per cent. per annum from the time when the respective calls became due, proceedings will be taken against you for the recovery thereof and without further notice to you."

Now that, continued his Lordship, was not in any way a notice in accordance with Article 23. It no doubt required him to pay the instalments alleged to be due, but it did not name a further day upon which such payment was to be made, nor state that, in the event of non-payment, the shares would be liable to be forfeited. But the further proceedings were even more extraordinary still. The letter of the 19th of March related to 2,000 shares, but Swaby denied that he was the owner of those shares. That was not seriously contested. It appeared that they were allotted to him in October, 1886, and on the 21st of February they were transferred to Watt, and this notice was not given until the 19th of March, 1888—more than a year after the transfer. In addition to the 2,000 shares, Swaby was also entitled to 400 fully paid shares. Now, by the articles shares were only forfeitable if the member holding them failed to pay calls on the day named. These 400 shares being fully paid-up, it was difficult to see how they could be forfeited at all. But on the 6th of April, 1888, this minute appeared in the minute-book of the Board of Directors:—"The solicitors of the Company reported that Mr. Louis Swaby had paid nothing with regard to the 2,000 shares applied for and allotted to him as against principal, interest, or damages resulting from non-fulfilment of contract, and it was resolved that the 400 shares standing in his name in the register of the Company be and they are hereby forfeited, and that intimation be accordingly sent to Mr. Swaby informing him that, as he is no longer a shareholder in the Company, he is neither entitled to act as a director nor to have the privileges of a shareholder." And on the 9th of April the Secretary of the Company wrote to Mr. Swaby as follows:—"I am directed to inform you that your 400 shares have been cancelled for claims due by you to the Company, owing to non-payment of the 2,000 shares applied for and allotted to you, and against which you have paid neither principal nor interest. You having accordingly ceased to hold any shares in this Company, are neither entitled to act as a director nor to the privileges of a shareholder."

It appeared also that there was an entry in the register of the Company opposite to the 400 shares to the effect that those shares were cancelled by resolution of the Board. It was not, said his Lordship, at all extraordinary that the plaintiff should have felt himself aggrieved, or that he should have brought this action, and when the matter came to be discussed counsel for defendants did not oppose that part of the application for an injunction. Then, on the 29th of April, in pursuance of that minute, Watt and Howell treated the plaintiff as no longer holding any shares or as being a director. The sole ground for that was the alleged forfeiture; but that was a nullity, and the defendants had no right to prevent the plaintiff from acting as a director, a position which he was entitled to hold. There appeared to be a struggle going on between the plaintiff and Watt and the shareholders who supported them respectively. The disputes were of a nature to be settled by the shareholders themselves, and his Lordship thought that early measures should be taken to bring the matter before them. Meanwhile, he had to determine the legal position of the parties. It appeared from the Directors' report that Mr. Watt and Mr. Brown retired by rotation, and on the 2nd of March, 1888, the following minute appeared in the minute book:—"Mr. John Brown intimated that, owing to the state of his health, he felt compelled reluctantly to resign his seat at the Board, and the Secretary was instructed to write a letter of condolence to Mr. Brown, and to intimate the sincere regret of his late colleagues at the step which he felt compelled to take." It was contended that that was a record of what took place at the meeting. Now, the articles provided that a director intending to resign should tender a written resignation at a Board meeting, and on the acceptance of his resignation his office should be vacant. It was quite plain that Brown did not tender any written resignation at a Board meeting, and that no resignation was accepted. His Lordship was not sure that the minute was a *bona fide* record of what took place. There were suspicions in his mind which which had not been removed by what had been told him by the Secretary of the Company in the box. The next meeting purported to appoint Mr. Howell a director of the Company. On the 16th of March, 1888, this minute appeared in the book:—"Present, Hugh Watt and George Howell.—A letter was read from Mr. L. Swaby intimating his inability, owing to serious indisposition, to be present, but stating that he was agreeable that Mr. Howell, M.P., should be a director of the Company. The Chairman then proposed Mr. Howell's election, and requested that gentleman to attend. Mr. Howell attended, and, having been informed by the Chairman that he had been appointed a director of the Company, returned thanks for his appointment, and took his seat at the Board." It was perfectly plain that there was no appointment. One man could not constitute a meeting, and the articles put it beyond doubt, because they required two Directors to be present before any business could be transacted. His Lordship then referred to further minutes of meetings, remarking that they were irregularly entered, and came to the conclusion that Mr. Howell had never been properly elected a director of the Company at all. He then referred to the proceedings at a meeting convened by a circular issued by the Chairman, and remarked that there was nothing in the articles authorising the Chairman to call meetings. His Lordship then read what purported to be the minute of a meeting held on the 11th of May, 1888, at which the Chairman expressed his opinion that Mr. Swaby was not entitled to be a director of the Company, and the minute further stated that the Directors approved a notice sent to Mr. Swaby in terms of the Board's resolution contained in the minutes of the 6th of April. So, said his Lordship, they purported to exclude the plaintiff altogether from acting as a director. That was one of the most surprising minutes his lordship had ever heard of. Could he believe it, after the melancholy exhibition which he had seen in the witness box? It was a mere story got up by Watt in order to protect his position, and to justify his high-handed proceedings with reference to the forfeiture of the plaintiff's shares. Taking that view, his lordship thought Howell had not been duly elected, and the plaintiff was entitled to an injunction in the terms of his notice of motion.

COMPANIES' MEETINGS.

UNITED TELEPHONE COMPANY.

The eighth annual general meeting of the United Telephone Company, Limited, was held at Cannon-street Hotel, E.C., on Tuesday, **Mr. James Brand** (the Chairman of the Company) presiding.

The **Secretary** (Mr. Thomas Blaikie) having read the notice convening the meeting,

The **Chairman** said: Gentlemen, you have all received a copy of the report, and have, no doubt, studied the accounts. I will not trouble you with going over these accounts just now, as I know that there is a gentleman, a friend of mine, in the room, who is going to make some inquiries as to the accounts by-and-by, and then I will endeavour by myself, or by some of my friends here, to answer him as well as I possibly can. After referring to the action in Parliament, he continued, I should say a word or two on a very important subject indeed, and that is as to our relations with our subsidiary companies. I was very much surprised to read in the report of the South of England Company, held on June 29, some remarks reported to have been made by the chairman of that company as to the relations of his company with the United Company. In reply to Mr. Billett, the chairman said this: Mr. Billett asked, "Has there not been some suggestion for these outlying lines to be connected with London?" And the chairman is reported to have said, "We are not an independent company so far as that is concerned—one-half will have to be run in the United Company's district. We have urged this matter on them repeatedly, but we get no further. With regard to Brighton, it is a joint line between the United Company and ourselves. Under the old arrangement we pay one-half, and derive no immediate advantage from it. It was an experimental line." Well, now, I feel sure that Mr. Bateson, the chairman of the South of England Company, would not willingly say anything but that which he believed to be true, and I can only suppose that he has forgotten the numerous interviews that we have had with him, and the proposals that we (the United Company) have made from time to time. Let me

Digitized by Google

tell you the fact as it stands. The United Company have, through the General Post Office, run a wire to Tilbury, among other places, at their own expense. On April 20, 1887, we wrote to the South of England Company offering to work this line at our own expense, and give the South of England Company half of any profit that was made, and to bear the whole loss, if any, ourselves; and I pledged myself to Mr. Bateson that if at the end of one year this manner of working this trunk proved unsatisfactory to him or his company, the whole matter should be revised and settled in a way that should be satisfactory to his company. Now, again, as to the Brighton wire. The General Post Office ran this wire also for the United Telephone Company. For two years, 1884 and 1885, we paid £446. 10s. per annum ourselves, rent to the Post Office. After that I arranged with the Chairman of the South of England Company that his company should pay one-half of the rent of the Brighton wire for 1886, and for all time after; but that the United Company would at their own cost fit up the necessary apparatus in the switch-room at Brighton Since then the South of England Company have worked the Brighton trunk wire without let or hindrance from the United Company. The United Company have paid the rent of the wire for 1887 and 1888 to the General Post Office; but we have not yet received any payment on account of these two years from the South of England Company. On June 29, the South of England Company wrote, agreeing in a great measure to certain proposals I had made in the letter I have mentioned on April 20, 1887, and yet at the meeting that was held on Friday ast—that is, the same day as that on which the letter was written—the Chairman of the South of England Company is reported to have said, in reply to Mr. Billett's question (who said: "Surely it could be no intention of the United to stifle its own children"), "We have proposed terms, and cannot get them"—that is, the United Company—"to second them at all. They refuse to enter on the subject at all. Since I have been in the chair, I have constantly urged this matter on the United Company, but have got no further to-day." Now, such statements as these, of course, are calculated to do great injury to the United Telephone Company in the eyes of you gentlemen, the shareholders, and of the public in general, and I think it is my duty, therefore, to contradict them, and to dwell at some length on this subject. A good deal of the property of the United Company, as you know, consists in its shares in the subsidiary companies, and we should be fools, indeed, if we tried to stifle our own children. It is not true that the United Company puts obstacles in the way of trunk wires. It is our own interest to push trunk wires with all our might. The National Company is as anxious in this direction as we are to join its different centres on to our system. On January 3 this year the United and the National Companies made arrangements mutually satisfactory for the erection and working of a trunk wire to Birmingham. I think I may say that the difficulties of the wayleaves are practically overcome. We have been met in a liberal spirit by the landowners with whose property we interfere, and we hope that within a month we may be able to commence the construction of the line. This line will provide nearly half the distance required to connect Manchester and Liverpool with London, and also enable Nottingham, Leicester, Derby, Sheffield, and other Midland towns to speak to London, as also the Northern district towns of Newcastle, Sunderland, &c. The same desire for inter-communication exists between the Western Counties Company and ourselves, and friendly negotiations are in progress for connecting London and Bristol, and the Western Counties have got as far as Bath. They have considered it best, however, before tackling with us the heavy outlay for the trunk wire to London, to connect their headquarters at Bristol with Newport, Cardiff, Swansea, &c., and the coal and iron fields of South Wales. You are aware that our agreements with our subsidiary companies prevent us running trunk lines from London to any town beyond 12 miles, and working without the consent of the subsidiary companies. They all know, however, that we are willing to join hands with them. I think I have said enough on this matter to show you how groundless are the curious statements that are constantly being made—[A shareholder: No; certainly not.]—that are constantly being made as to the dog-in the-manger policy of the United Company. It is hardly possible for the shareholders to realise the difficulties that we meet with and have to overcome; and I wish the shareholders would lend us their aid to a greater extent than they do. It is surprising how few of the shareholders are subscribers to our lines. I do not think that 10 per cent. of our shareholders subscribe to our exchanges. However, we do the best we can, and during this year we have increased our mileage of wire from 7,500 to 8,700 miles. There are at present free call-rooms for the use of subscribers existing at Oxford-court, Chancery-lane, the Law Courts, the House of Commons, Regent-street, and Edgware-road, and arrangements have been made, in deference to the wishes expressed by some of the shareholders and as a matter of experiment, for establishing paying call-rooms at Kilburn, Balham, Limehouse, Earl's-court, Denmark-hill, Holloway, Brixton, Greenwich, Notting-hill, Croydon, Richmond, and Brentford. I must tell you that these paying call rooms have not been so much pushed by the United Telephone Company as, perhaps, by some of the other companies further north and west. Our opinion is that these call-rooms in London, as a matter of revenue, will not be very successful. In the North they have proved a good source of revenue, but then that is because of the trunk lines existing between town and town, and the public who are not subscribers take advantage of the call-rooms to communicate from town to town, and are willing to pay 3d., or 6d., or 1s., or whatever it is—I don't know exactly. As far as I know, the call-rooms established in the towns have not been made much use of for local communication. However, we think it is a good thing to try the experiment, and if it does not pay us directly by revenue we think it will pay us by educating the people more and more in the inestimable blessings of the telephone. Well, then we have put up during the year new iron derricks, at great expense, of course, to replace those derricks that were destroyed in the snowstorm. We have got one at Oxford-court, another at Queen Victoria-street, Mincing-lane, East India-avenue, Cornhill, the Hop Exchange, and Smithfield, and there is one in preparation for Heddon-street. We have opened a new exchange at Smithfield with a largely-increased capacity, and the lines have been transferred from the old exchange to the new. With the view of centralising the work of switching, three minor exchanges have been closed. These are Leadenhall-street, Stratford, and Shadwell. The exchanges having been transferred to the larger exchanges, a new multiple switch-board has been erected in the new exchange at Smithfield, and preparations are well advanced for erecting multiple switch-boards at East India-avenue, Westminster, and Chancery-lane. We have opened, and got in very good order now, a new trunk line to Croydon on our own poles, free from the induction of railway poles and other electrical wires, and it is working very well. It has only been opened about a month, and we hope it will be a source of good profit to us. Some remarks were then made on the proposed amalgamation scheme, when the Chairman said: I know very well that this matter should be settled promptly, for until it is settled it retards the development of the Company's business in new lines and connections in the direction of which I have already spoken. You will have seen from the accounts laid before you that during last year we have expended nearly £29,000 on this account, but this has been solely within the metropolitan area. The development of the system of trunks will, of course, involve a large expenditure of capital, and one considerably larger than we can provide, as we have hitherto done, out of the sums debited to revenue for depreciation and other things. If and when it is necessary to raise money for this purpose, we will, of course, call you together and ask your advice on the subject. Well, then, as to law during the year, Mr. Winterbottom has sent me this report, which I will read to you. He says: "Since the decision of the Court of Appeal in favour of the Edison patent, in the action against Messrs. Bassano and Slater, of Derby, there has been no serious attack upon the Company's patents, and the Directors were in hopes that the many ingenious attemps to get outside the patents were at an end. However, at the beginning of the present year Mr. Campbell Swinton, a Scotch gentleman, brought out an instrument, and formed a small company to manufacture and sell it, and as the company was beginning to do business on a somewhat extensive scale, it became necessary to take action. The Directors are glad to say that an *interim* injunction was promptly obtained, which has, for the present, put an end to further sales, but the defendants appear inclined to fight the whole question over again. As the question of the validity of the Company's patents has already been decided by the Court of Appeal, and the Directors had the best possible advice (that of the present Attorney-General and other well-known counsel) that the instruments are infringements, they are in no way anxious about the result. At the same time, it is much to be regretted that the law allows limited companies without any uncalled capital to put a patentee to all this expense after the question has already been litigated and decided. Well now, I think I have said enough for the present; but before I move the first resolution—that the report and accounts be taken as read—I shall be glad if any gentlemen have any questions to ask, that they ask them now. I was waiting to see if any questions were going to be asked about the accounts; but in order to have this brought about I have to move: "That the report and accounts be received and adopted, and that a dividend for the half-year ending the 30th April last of 10s. per fully-paid share, and of 5s. on the new shares, less income-tax, be paid—making a total dividend for the year of 15 per cent. on the paid-up capital of the Company."

Mr. James Staats Forbes seconded the motion.

Mr. Sichel offered apologies for opening the discussion, and said he would only start the hare and leave gentlemen on the other side of the table to hunt it. He would begin with the £15,000 for snow expenses last year, which seemed to double the amount which the Chairman at the meeting last year stated was the probable cost of the loss involved—the bill had pretty well doubled itself. He supposed there was some good reason why this was done, but the £15,000 charged this half-year was equal to 3 per cent. on the capital of the Company, and if that had not appeared in the accounts, they would have had a bigger reserve, or they might have been favoured with a bigger cheque for dividends. The Chairman had remarked that he was anxious that the public at large should value the benefit of the services of the Company, and have some understanding of the value of it. With full diffidence, he ventured to think that the public were fully alive to the value of the telephone, and that the place where there was a want of sufficient knowlegde of the value of the telephone was on the other side of the table. He was told that the call offices of the metropolitan area were a loss of revenue, as they led to a loss in regular subscribers; but, as an individual member of the public, and as one coming in contact with a great many who used the telephone, he thought an enormous increase of call offices would be a boon, and ought to be a source of great increase of revenue to the Company; and he would couple with that idea the system of issuing yearly tickets to subscribers at a price of four or five guineas per annum, entitling the holders to employ any call office within the area of the metropolitan district when they wished. If the Board would employ canvassers to increase their subscribers they would find that scarcely a large retail shop in London would not find it a necessity, almost, to take up the idea. Members of clubs would find the system the greatest convenience, and he believed at the Stock Exchange they would find 1,000 or 1,500 members would like to have their residences in connection with the centre of their city occupation. They ought to get 10,000 subscribers who would be pleased to have a telephone ticket in their pockets. He did not claim originality of the idea, for he had seen it employed in Paris. He hoped the Board would entertain it, and that they would appoint a gentleman solely in carrying it out, and pay him in proportion to the new business he brought to the Company He was satisfied that the business was capable of immense extension. Any gentleman who had been in the States knew there was not a two-penny-halfpenny druggist, or grocer, or keeper of dry-goods stores

Digitized by Google

who did not constantly use the telephone. In New York, which was only two thirds the size of London, the number of calls was five times as much as in London, but what the American found a necessity was not within the reach of Englishmen, and Englishmen were so stolid and stupid that they did not see the advantages. It was entirely by being restricted that the Company had not the business that it ought to have. It was particularly necessary that they should increase the number of their subscribers in view of the death of their patents three years hence. At the end of that time it would be the connection that would be valuable, and they should be in a better position having regard to the ultimate fate of the Company in being bought up by the Post Office.

Mr. Begg said his friend the Chairman had made an allusion to him in his opening remarks, and he wished to ask some questions. In order to make his criticisms definite, he had written the questions down, and the Chairman knew what questions he proposed to ask. He suggested that the Chairman now answer those questions, and he could follow with any criticisms he might wish.

The **Chairman** said Mr. Begg's first question related to the reserve account—how was it made up? Well, it was made up partly of sums written directly off profit for the year; partly in sums put into account for depreciation; partly in profits derived by the sale of instruments to the Admiralty or to certain railways; and partly from the premiums obtained on the issue of new shares.

Mr. Begg: How is it invested?

The **Chairman:** It is in the air; it is in the poles, the derricks, the wires, and generally in our business.

A Shareholder: So that it is really a surplus capital account?

The **Chairman:** Yes; whichever way it is stated, practically it is the same to the shareholders. Mr. Begg next asked as to Directors' fees, "Are any special fees or allowances drawn by any of the Directors beyond those shown in the accounts?" Well, the only special fee that was drawn by any Director was that by the Managing Director, who did not share in the fees of the other directors, but was paid under a separate arrangement, which was that they paid him £1,000 per annum, and 2½ per cent. on the divisible profit, after 10 per cent. had been paid to the shareholders; in addition, he was paid about £400 for travelling expenses and expenses in London. This year the amount paid him altogether had been about £3,000.

Sir Julian Goldsmid: It is an illegal payment.

Mr. Forbes said it was in accordance with the articles. He read a clause to the effect that the Directors had power to appoint a Managing Director from among their number, on such terms as they might decide.

Mr. Sichel: Does the amount paid to the Directors and the Managing Director come to £15,000 a year?

The **Chairman:** It is nearly £10,000. The Chairman continued: Mr. Begg said the royalties did not appear to have been accurately adjusted, and he asked were any of the companies in arrear, or were accounts in dispute, like that of the South of England Company. As he understood it, there was no discrepancy—it was the way of putting down the royalties. As regarded the other matter, there were sums remaining to be paid by the affiliated companies, and these appeared in the balance-sheet among sundry debtors. In one case a considerable amount was involved, but inasmuch as it was precisely similar to a case concerning the Lancashire and Cheshire Company, which was decided in their favour by the Courts, he did not anticipate any difficulty in settling the matter with other companies on the same basis. Mr. Begg next referred to the charges and working of the metropolitan area, and said they showed large increases for salaries, wages, &c. —say, £7,000—while rentals increased (cash) £2,431, or per rent roll, £6,851 only. Result—less net revenue by £3,302 in cash this year. Why, he asked, was there such an increase? He (the Chairman) had referred this question to Mr. Welton, whose explanation was that these charges were not merely for the expenses of collection of dividends and royalties, and he considered them very moderate indeed. The accounts were made up on the basis that the two revenue accounts belonged to two separate companies. The working charges were made to look worse this year because they compared with the year 1886. Last year the working expenses were less than usual, because during a good part of the time they were rebuilding and maintaining, and in the rebuilding, of course, the maintaining was included, and put into the expenses of the good old snowstorm. They were rebuilding, not maintaining, so the revenue paid for it. Some of the expenses also arose from opening outlying centres. With regard to capital expenditure, Mr. Begg said, "This seems to bring a much reduced increase of revenue—why?" He asked Mr. Welton to explain this.

Mr. Welton said he had in his hand a paper which showed the extent of the fresh exchange lines was 749 new exchange lines, costing £12,760, but the number cancelled was 422, the loss of revenue on that being £9,647, so that the net benefit was £4,113. In the same way they provided 287 fresh exchanges, costing £5,712; but the number cancelled was 138, the rental on which would be £2,975, the net benefit being £2,737 in the year, and the total increase on revenue being £6,851. That would be due to many customers having withdrawn or become bankrupt.

Mr. Begg said he would offer a few remarks. Mr. Brand had paid him a compliment to which he did not think he was entitled. He held that the management of the Company on the one hand was extravagant, and in the second place inefficient. With regard to extravagance, the reserve fund, Mr. Brand explained, consisted principally of two items: there were in it the premiums on the new capital which the Company issued and other sums carried to it for depreciation. He only found the record of one such sum, and that was in 1884; since then the reserve account had been added to without any particulars being given. In 1884 the item placed to reserve was called reserve against depreciation. Depreciation meant waste, and he said that any sum which was depreciation being carried to the account called reserve was misleading. It was a very good thing to have a reserve against a rainy day—or, perhaps, in their case he ought to say against a snowy morning—but the reserve ought to be consolidated and substantial. Then as to premiums on new shares, that was a fair subject for the reserve fund in a sense, but it was a capital reserve, not revenue. They never saw it classed as revenue. But it was not a proper financial entry; it was not a reserve fund that could be used for the ordinary purposes of a reserve. With regard to the Directors' fees, he would leave them to speak for themselves. He thought if they had no complaints of the management, and were a thoroughly prosperous company, with a growth of revenue, they might be contented that the fees were not too large. He did not think even then they would be thoroughly able to be defended; but a defence might be set up for them. With regard to the royalties, the Chairman said the accounts were adjusted to date; that accounted for something in the figures which struck him as rather peculiar. Speaking from memory, the revenue brought in respect of royalties from the sub-companies during the past year represented an increase of £5,600. The royalty might be taken roundly at 10 per cent., therefore that represented £50,000 additional subscription in the sub-companies; but he found, in looking at the revenue of the sub-companies for last year, the total revenue of the companies, other than this, was £200,000. Therefore these companies must have increased their revenues by £50,000 during the past year. Either they had, or they had not. If they had, so much the worse for this Company, because they had only got an increase of £2,600 in their accounts other than royalties; while if they had not, the sums in respect of royalties had been brought unduly into this year's account. The Directors must settle which was the correct reading of these figures. The question of general charges was a difficult one to go into. They might go into the figures all day and not come to a satisfactory conclusion. It seemed that the snowstorm was made to pay for all. They had, first of all, £15,000 charged last year for the snowstorm, and they were told at the last meeting—and nothing could have been clearer—that the whole thing had been charged in the accounts of the year, that was the end of it; and quite right, too, if it had been. But this year a fresh item of £15,000 more was charged for the snowstorm; and whenever they approached anything in the accounts, they had the whole matter jumbled up with the snowstorm, and it was exceedingly difficult to arrive at any localisation of this extravagance. With regard to general revenue, it had been said that this Company consisted of two companies—the Telephone Exchange and the management of the subsidiary companies. What did the other part of the Company's business consist of? Collecting royalties, distributing dividends and taking actions He did not know that the actions were a mistake, because, of course, they must defend their patents; but he saw no justification of an expenditure of £6,000 or £8,000 in salaries, &c. The new capital recently spent brought in very little. Taking the accounts of four years, they found that whereas in the two last years there was an expenditure of £65,000, which had been debited to capital account, had only produced an increase in revenue of £12,000, and that revenue had not been realised, but was only stated on paper; it had not come into the treasury. Taking the two previous years they found that an expenditure of £57,000 brought in £22,000 of new revenue. The explanation might have been in some measure the snowstorm, but he would point out that the revenue was not actual but estimated. After quoting the comparative statement in the accounts to show that the expenditure of capital in the latter period of the Company's existence was not followed by an increase of revenue that ought to result, Mr. Begg said the explanation was probably that a greater number of lines were given up. But this was the strongest condemnation of a company's management. He knew a good deal of telephones in the provinces, having worked amongst them very hard for the last eight or ten years, and he knew that anything like the giving up of a line was an exceedingly rare thing. The necessity for the constant building of new lines and the throwing away of old lines was probably the secret of this Company's discrepancy, and it was an exceedingly bad tribute to the management of the Company and the odour in which it was with the subscribers. So much for the accounts. Now, with regard to the general management of the Company, he would like to say a word or two on this subject. It seemed to him that several points required attention. The Directors some months ago issued a circular, in which they invited suggestions as to the management, and in what respect it could be improved. He took the liberty of replying at some length. The first point he took was the question of the call offices referred to by another speaker. Now, the Directors of this Company seemed to be entirely ignorant of what was going on round about them. Throughout the provinces these call offices had been in existence many years, and he was satisfied that they had been, and were now, a large advantage to the companies using them, and were successful. Three years since they had call offices in Edinburgh, and he knew that they were a constantly-growing source of advantage. The call offices he meant were for the use of the public, not merely for subscribers, as in the case of this Company, and they had them in Manchester, Liverpool, Glasgow, Edinburgh, &c., and one could step in here and there, pay his 6d. or 3d.—whatever it might be—and have his conversation. They were used for local needs, and not, as the Chairman said, for trunk wires. He was glad to find that call offices were now being established by this Company, and hoped they would go on with them. Then there was a question of continuous service. He laid it down as a general proposition that there was not a telephonic exchange that was not open from one year's end to the other continuously, except London, and London was the place of places where such a service was required on Sundays; and for two reasons: in the first place, there was no delivery of letters on that day, and they could scarcely send a telegram on Sunday. The cost of making the system continuous would be practically nothing—not more than £500 or £1,000 a year to establish it at once. The only other question he would trouble them with was the question of trunk wires. They had trunk lines everywhere but in London. Every town of magnitude had

Digitized by Google

telephonic communication except London, and here in London there was not a single trunk wire line, except Brighton, which was purely experimental.

The **Chairman**: Oh, no.

Mr. Begg: How many calls do you get?

The **Chairman**: There are a good many calls; it is not our fault if calls are not made. We cannot make the people call.

Mr. Begg remarked that the Chairman said he was willing to join hands with the sub-companies about the trunk scheme; but willing to join hands was not the attitude of the Board of a telephone company. The Board should insist, and if others would not go ahead in the matter compel them to. They could not get a communication of any sort except in Tilbury—and some of them wished they had not got that—and Brighton. He would impress on the Board the absolute necessity of something being done in the matter at once. The greatest bulwark of this Company was its patents, which were three years within their expiration, and unless they made good use of the short remaining time they would not get from the Government, which, no doubt, must ultimately buy the property, anything like what they ought to get. He did not wish to make a hostile motion, but should like to test the feeling of the meeting, and would formally move that the accounts be not passed, and that a committee be appointed to investigate the affairs of the Company and report to the shareholders.

Sir Julian Goldsmid said at the last meeting he made complaints which the Chairman said would be considered. They had been considered by being ignored. He pointed out last year that there was no company with a capital of half a million whose directors were paid excessive sums. He accused the Chairman of concealing the fact at the last meeting that the Managing Director was paid a large sum over and above the Directors' fees.

The **Chairman** denied this, and said he stated definitely how the matter stood.

Sir Julian Goldsmid further stated that after the last meeting one of the Directors, Mr. Quilter, said he quite agreed with him that the Directors were paid too much. He urged that although the fees were provided for in the articles, the articles could be altered. Of the profits made by the Company, the Directors had had a third. It was a a disagreeable thing to make an attack on men of high standing; but he felt that in a company of the sort they had no example of directors being so extravagantly paid. He thought, therefore, that the articles should be altered so that there should be some revision of the accounts. He seconded Mr. Begg's amendment.

Sir Edwin Galsworthy was surprised at the accusation of the last speaker, that the Board kept back the fact that the Managing Director was paid a large sum for his services. That was an unfair charge. He held that the charges of extravagance and inefficiency had not been proved, and as to the Directors' fees, he urged that if they wanted to alter them, let them go the right way to work, and alter the articles of association.

After some further discussion,

The **Chairman** said he would ask his friend, Mr. Forbes, to answer some of the questions asked. He commented on the unexpected violence of the attack on the Directors, when he believed they were giving the shareholders a good account and declaring a good dividend. With regard to the fees, the Directors felt they had made a bargain with the shareholders, and they did not see that under the circumstances of the case they should be called upon to give up the profits of the bargain. It was made some years ago when the invention was first bought, and the Directors had spent a good deal of time and money in developing the thing, which was then utterly unknown in this country. The Directors had kept to the bargain; they had not sought to increase their remuneration, though in some ways he thought they might have done so, and they certainly did not expect it broken on the other side. If the amalgamation took place, there would be new articles of association, and the shareholders could reconsider the question then if they chose. The Chairman then proceeded to read from the transcript of shorthand notes of the last meeting, and showed that the question of the Managing Director's salary was raised by the late Mr. William Abbott and explained by the Chairman.

Sir Julian Goldsmid said he left the meeting before Mr. Abbott spoke.

Sir E. Galsworthy: That does not justify the shareholder in imputing concealment to the Board.

The **Chairman**: I hope Sir Julian Goldsmid will withdraw such an imputation.

Sir J. Goldsmid: Sir Edwin Galsworthy seems to have amused himself by finding out a mare's nest. I did not hear the inference to the matter at the last meeting.

Sir E. Galsworthy: That is not a justification for the charge. I do not know about mare's nests, but I think it would only be an act of decency now to withdraw the charge. The Board deserve our protection.

Sir J. Goldsmid: The Managing Director's salary ought be shown in the accounts. I dont' want to make any charge.

The **Chairman**: But you did do it thoroughly. As to putting it in the accounts, there would be no objection; but surely there was no reason for making such observations as you did. The Chairman then turned to other points raised, and with regard to the snowstorm, the loss was estimated at £15,000, and £5,000 were put aside, which they had expended to within £160. Then, the meaning of the further £15,000 was this: while they were mending their wires they avoided as much as possible calling on subscribers to pay their subscriptions, which, as a rule, were paid beforehand. When they got their system in order they began to collect the money, when they found their large customers demanded a reduction for the three months' delay in the system, and the Directors had to make the best arrangement they could, and allowed about one and a half or two months' subscriptions to people instead of giving them back any money; they gave a 14 months' receipt for 12 months' use.

Mr. Forbes said he was sorry Sir Julian Goldsmid had left the room, because he was the parent of what must be treated as the personal part of the discussion. He was a lawyer, a member of Parliament, a director of a powerful company, and a man of great position, and he would acquit him of any intention of malice aforethought, to cast imputations or make misstatements. He was sorry a man in his position should hazard the statements and imputations that he had done. The contract with the Directors was a legal and binding and moral contract, which they were bound to carry out. £1,500 a year was divided between seven gentlemen. Now, he would undertake to say that in one or two crises in the history of their Company one single hour's work would have justified their Chairman and himself in taking a good many £1,500, and they would find that out in future, too. Why were they taking these large fees? Because, first of all, they had gone into the swim with the shareholders and held a very large number of shares, and therefore they had their shares, and they found the brains and knowledge with which to carry on the business, and had the responsibility of working the Company's money to their advantage. Had they worked it to their advantage? Well, they got £1,500 a-year up to the time when the shareholders received 10 per cent. The averages were the things to look at. They got for five years, during all the labour, anxiety, and discouragement and difficulty of making this Company—because they made it—£210 a-year apiece on the average. He would ask which of them, having the capacity and knowledge, would do this sort of work for £200 a-year? By dint of their brains and knowledge they had got the shareholders' dividend up beyond the 10 per cent., and had become partners; they were to have 20 per cent. for all the money they made after payment of 10 per cent. He would defend that bargain against all the world. The Directors accepted the responsibility and labour of the business on that bargain, which, he said, was a reasonable bargain, and redounded enormously to the interest of the Company. Surely men of business and men of honour were not going, because one party to the bargain had reaped the benefit of it, to begrudge them the result! He would not hold such an opinion of men of business and men of honour. Surely the shareholders had received more than 10 per cent. It was the Directors' moral and legal claim to be participators in the further profits; and what had they got? For three years £750 each. Was that undue remuneration under such circumstances for such men? If they thought it was, let them find other men who would have done for them what the Directors had done in the past, and were capable of doing in the future. Amalgamation had been referred to; but not five men in the room knew what dangers surrounded the Company. They had got three years for the patent to run; after that the whole world might be then competitors, including the Post Office. Were the shareholders going to discourage the Board in their efforts to provide for that period? They had made a substantial property. The £5 share was worth £15; they had a 15 per cent. dividend, and a reserve fund of over £100,000. That was not a bad outcrop of a company which had been eight years in existence He said these things that Sir Julian Goldsmid and the critics might think about them. Mr. Begg's criticisms would have been admirably apposite if he had known anything about the business. Mr. Begg had remarked on the manner in which the Directors had neglected the Company's interests in not developing call offices. If Mr. Begg had the figures before him that he had got, and the knowledge he possessed, he would not have been so very much surprised. He would say, "What is the cream of this business?" And as long as he could skim cream he did not want to skim milk. The cream of this business was the exchange. The exchange returns were the largest income of these companies, in the relation of all to nothing, and these call businesses were a mere *bagatelle*. He found the Lancashire and Cheshire exchange line had a gross income of £81,000, and the trunk wire and call department was £6,500. In the National the gross income was £90.000, and their fees for messages were £1,800. This company, with 8,700 miles of wires, 4,835 exchange subscribers, and 21 exchanges through which the whole of this enormous number of calls had to be forced, was to render the service—not yet nearly as efficient as it ought to be and might be made to be—useless by letting Dick, Tom, and Harry go to the call office, and take possession of wires which were already flooded with their subscribers! That was really the position, but if Mr. Begg had any greater responsibility than talking about it he would not say what he had. The Company had got to force all their works through 21 exchanges—exchanges the difficulty of which was not equalled by any city in the world. They were very differently situated to the cases Mr. Begg had quoted, and they should compare like things with like. There was no comparison of any city or place in the world with London. Look at the mere question of way-leaves! Everything this Company had to do was on sufferance. Their services were multiplied, because they could not get the shortest cuts. Let every man of brains, of knowledge, of temper, and inquiry go into the thing, and see what was to be done in this concern! He hoped Mr. Begg was not going to press for a committee to enquire into their business. He, for one, was not going to submit to any such committee. Either the Directors knew their business and were worthy of confidence or they were not. When the shareholders thought they were not, let them turn them out and let in Mr. Begg, or anyone else they liked. He knew of no form of censure so unjust and so insidious at this committee of inquiry. In order that the shareholders might know that the Directors were not greedy nor negligent of any promises they had made, he would say they had considered the "enormous" payment of the "dreadful" Directors. He, for one, was not going to work for £200 a year; he would carry his brains to a more successful market. The Directors knew the defects of their system; they new its difficulties. The shareholders knew its defects, but did not know its difficulties—that was the difference, and anyone put in to supersede them would very soon find out the difficulties, and would have to acquire it at the shareholders' cost, and slowly—what the Board had acquired after long years, and which was a possession that nothing but long service could give. He therefore asked the share-

Digitized by Google

holders to consider whether it was worth while to join with Mr. Begg and upset the present Board. Let them recollect for a moment that they were a Company which had excited jealousy all round by the large dividend they had paid, and also that they would be face to face with wholesale competition in three years, and with a Government who would probably use their powers to obtain this property. The future would require all the brains and knowledge that the Company had got in their present Directors, and it would be no favour to have paid them their fees if, as the result of their exertions, they succeeded in carrying the Company on up to the time when it was taken over by the Government.

Mr. Begg said Mr. Forbes had made a statement to the effect that he was ignorant of the subject. ("No, no.") He would ask his friend, Mr. Brand, to state whether he did not know he had been ten years actively engaged on telephone work. He might say, as the point had been raised, that he knew down to the minutest detail all the inner working of every item.

The Chairman said he told his colleagues that Mr. Begg was a fair criticiser, and had a good d al of experience. Mr. Forbes did not mean he was ignorant of telephone work, but of the many difficulties the Company had to combat, and he said so too

After some further debate Mr. Begg offered to withdraw his amendment, but the Chairman put it to the meeting, when it received but a small amount of support.

The original motion was then agreed to.

Mr. John W. Batten and Mr. Frederick R. Leyland, the retiring Directors, were re-elected, as were also the Auditors.

Sir E Galsworthy proposed a vote of thanks to the Chairman.

Mr. Begg seconded the motion, which was carried, and the proceedings then closed.

SOUTH OF ENGLAND TELEPHONE COMPANY, LIMITED.

The fifth ordinary general meeting of this Company was held on Friday at Winchester House, Old Broad-street.

Mr. D. Owen Bateson, who presided, stated that their exchange lines had increased from 1,130 in 1887, to 1,521 in 1888, and the private lines from 348 to 386. In the latter item the new lines had been many more than were indicated by the figures, but there had been an unusual number of withdrawals, occasioned, he supposed, by some of their subscribers having been induced by apparent cheapness to try some other instruments. He did not think there would be a continuance of the withdrawals, and some of their former subscribers had returned to them. Their gross rentals stood at £19,325, being an increase over those of 1887 of £4,135. The management and working expenses had been £5,099, or £901 more. Some of the extra expenditure was due to charges for strengthening their system where they had found it necessary. The whole of the 20,000 preference shares of £5 were now issued. It would be necessary before long to call another 10s., but the Board would delay making the call as long as possible, knowing that the 6 per cent. interest would be an additional charge on the Company. Their next trunk lines would be between Canterbury and Ramsgate, Deal, and Ashford. Their line between Margate and Westgate they had been obliged to abandon owing to the obstructive policy of the representative of a charitable institution, but that was quite an exceptional case. The exchange in Canterbury promised well, and they were making that a centre from which various lines were to radiate—namely, to Dover and Folkestone, in the first place, and that portion of the scheme was nearly complete. Subsequently, lines to Ramsgate and Margate would be run; also to Deal, Sandwich, Ashford, and probably Faversham. If they carried out that plan, each place on the radius would be able to speak to subscribers at all the other towns on the radius. In many of their districts they had established fee-call offices, worked by automatic call-boxes, by means of which anyone, whether a subscriber or not, on payment of 3d. for local or 6d. for trunk communication, could call up subscribers on the exchange, and have three minutes' conversation. They had paid two half-yearly dividends on the preference shares, leaving them with £3,115. They had placed £500 to reserve—a fund which would enable them to meet any disaster without jeopardising their dividend; and they proposed to pay a dividend of ½ per cent., carrying forward £1,115. He concluded by moving the adoption of the report.

Mr. Alexander MacGregor seconded the motion.

In answer to questions, the **Chairman** stated that they could run their lines to the 12-mile radius, but they could do no work in the district of the United Company without the consent of that Company. They had repeatedly endeavoured to urge the matter on the attention of the United Company, who, however, simply declined to discuss the subject with them. With regard to a consolidation of all the telephones, there had been a meeting of the subsidiary companies and of the United Company, and a sub-committee had been formed to investigate on what terms such an arrangement could be carried out.

The motion was adopted, and the dividend recommended was declared, the retiring Director and Auditor being afterwards re-appointed.

LONDON PLATINO-BRAZILIAN TELEGRAPH COMPANY.

A general meeting of the London Platino-Brazilian Telegraph Company, Limited, was held on Thursday week at Winchester House, Old Broad-street, E.C., **Capt. Francis Pavy** in the chair, for electing new directors.

The **Chairman** stated that the agreements between the Company and the Western and Brazilian Telegraph Company had been carried into effect, and out of 38,348 shares forming the Platino capital, 33,515 had been exchanged for Western and Brazilian shares, or 4,000 shares beyond the three-fourths requisite to give effect to the agreements. The agreements had been duly registered and lodged at Somerset House, so that matters were now in order and the exchange virtually completed. In these circumstances, having carried over the agreements, it was only left, according to the arrangements, for the present Directors to resign and for others to be appointed. He concluded by moving a resolution accepting the resignations of Sir John Pender, Captain F. Pavy, and Mr. John Hollocombe, and appointing Lord R. Howe Browne, Major A. Wood, and Messrs. W. S. Andrews, C. W. Earle, D. W. Goodsall, and H. Weaver, Directors of the Company.

Mr. J. Hollocombe seconded the motion, which was carried unanimously.

CITY NOTES.

Removal.—The Schanschieff Electric Light and Power Company, Limited, is removing from 65 to 44, Basinghall-street.

West Coast of America Telegraph Company.—The receipts of the West Coast of America Telegraph Company for June were £6,225.

Brazilian Submarine Telegraph Company.—The traffic receipts of the Brazilian Submarine Telegraph Company for the week ended June 29 amounted to £3,941.

Manitoba.—Messrs. Robert A. McLean and Co. have notified for payment the half-yearly interest on Manitoba Electric and Gas Light Company First Mortgage Debentures.

Direct Spanish Telegraph Company.—The estimated receipts of the Direct Spanish Telegraph Company for June are £1,690, against £1,561 in the corresponding period of last year.

Eastern Telegraph Company.—The Eastern Telegraph Company's traffic receipts for the month of June, 1888, amounted to £48,096, and to £45,426 in the corresponding period of 1887.

Telegraph Construction and Maintenance Company. — The Directors of the Telegraph Construction and Maintenance Company have decided to pay an interim dividend of 12s. per share, on the 17th inst.

Eastern Extension, Australasia, and China Telegraph Company, Limited.—The traffic receipts of the Eastern Extension, Australasia, and China Telegraph Company, Limited, for the month of June, 1888, amounted to £41,764, and to £35,138 in the corresponding period of 1887.

West India and Panama Telegraph Company.—The estimated traffic receipts of the West India and Panama Telegraph Company for the half-month ending June 30 are £2,553, as compared with £3,052 in the corresponding period of 1887. The March receipts, estimated at £7,036, realised £7,051.

Cuba Submarine Telegraph Company.—The number of messages passing over the lines of the Cuba Submarine Telegraph Company during June was 4,114, estimated to produce £3,000, against 3,613 messages, producing £2,929, in the corresponding month of last year. The receipts for March, estimated at £3,800, realised £3,835.

United River Plate Telephone Company.—The report of the United River Plate Telephone Company, Limited, showing the result of the operations during the sixteen months ended the 31st of March, states that there is a net profit of £24,166, out of which an interim dividend of 2½ per cent. was paid in October, the actual available balance being thereby reduced to £17,916. The Directors recommend a further dividend of 4½ per cent., being 4s. 6d. per share, tax free, £5,000 being placed to a depreciation and renewal fund, and £1,666 carried forward.

The Buckingham Electric Light and Power Supply Company, Limited.—Registered by Digby and Liddle (agents for Henry Small, solicitor, Buckingham). The capital of the Company is £5,000, in shares of £1 each. Object: To carry on at Buckingham and elsewhere, in the county of Buckingham, the business of an electric light and power supply company in all its branches, and in particular to construct, lay down, erect, establish, fix, and carry out all necessary cables, wires, lines, primary, secondary and other batteries, accumulators, lamps, apparatus and works, and to generate, accumulate, distribute and supply electricity; and to light streets, wharves, markets, churches, chapels, shops, buildings, and places both public and private.

Electrical Purification Association, Limited.—Registered by Hargrove and Co., 3, Victoria-street, Westminster, S.W., with a capital of £15,000, in shares of £1 each. Object: To acquire certain patents Nos. 1,333, 15,760, 15,939, 472, and 1,105. The patents generally relate to improved means of oxidising and decomposing by electrical action organic matter and inorganic salts in sewage water and other liquids, and the production of certain products therefrom, and improvements in the means or appliances for treating sewage by electrolytic action, and for the disposing of the deposits thereof. The first subscribers are:—

	Shares
W. Webster, electrician, Lee Park, S.E.	200
T. Slater, engineer, Westminster	1,000
J. Crow, secretary, 54, Wickham-road, Brockley	1
J. H. Jones, Cairo, Egypt	1
A. Cassaveti, 6, Clarendon-place, Hyde-park	1
W. Porter, Baring-park, High-road, Lee, S.E.	1
E. Webster, 9, Lee-terrace, Lee, S.E.	1

The number of directors shall not be more than four nor less than three. Wm. Webster, Edwin Webster, Thos. Slater, and Alexander Cassavetti shall be the first directors. Until otherwise determined by extraordinary resolution, the directors for the time being shall continue to hold offices subject only to clause 57 of the Companies' Act, 1862 (Table A). Any vacancy in the Board of Directors shall be filled up by the Company in general meeting.

PROVISIONAL PATENTS, 1888.

JUNE 22.

9141. **A new or improved automatic electrifying apparatus.** Charles Huelser, of the firm of Huelser and Co., 142, Fleet-street, London. (Julius Müller, Germany.)

JUNE 23.

9177. **Improvements in the screws and screw nuts of the stay rods and swivels or stay fasteners of telegraph poles; which improvements are also applicable to the screws and screw nuts of other articles exposed or liable to be exposed to the weather.** Howard Cochrane Jobson, 7, Staple-inn, Middlesex.

9206. **Improvements in galvanic elements or batteries.** Carl Lütcke and Paul George, 166, Fleet-street, London. (Complete specification.)

JUNE 25.

9250. **An improvement form of voltaic cell, the positive element in which consists of an amalgam of mercury with zinc and sodium, or zinc and potassium.** Sir Charles Stewart Forbes, Bart., 21, Finsbury-pavement, London,

9254. **Controlling devices operated by means of the thermic effects of electric currents.** Bernard Mervyn Drake and John Marshall Goram, 2, Princes Mansions, Victoria-street, Westminster, and Edward Manville and William Leonard Madgin, 36, Albert Embankment, London, S.E.

JUNE 26.

9277. **An electric automatic annunciator.** Henry Binko, 34, Leadenhall-street, London.

9303. **Filling lining and non-conducting material.** Henry Ward Johns, 76, Chancery-lane, London, W.C. (Complete specification.)

9308. **Improvements relating to dynamo-electric machines.** Joseph Edmondson, 45, Southampton-buildings, London, W.C.

9332. **Improvements in electrical connection of railroad rails.** Frederick Stitzel and Charles Weinedel, 18, Buckingham-street, Strand, London, Middlesex. (Complete specification.)

9333. **Improvements in and relating to electric arc lamps or lighting apparatus.** Henri Pidot and Henri Pautier, 45, Southampton-buildings, London, W.C.

JUNE 27.

9381. **Improvements in electric batteries.** Alexander Imschenetzky, 6, Bream's-buildings, Chancery-lane, London.

JUNE 28.

9405. **A method to enable alternating currents of electricity to be utilised for charging electrical accumulators.** R Frederick Yorke, Cecil House, Redhill, Surrey.

COMPLETE SPECIFICATIONS ACCEPTED.

JUNE 29, 1887.

9264. **Improvements in electric clocks.** James Grieve Lorrain, Norfolk House, Victoria Embankment, London, W.C.

JULY 29, 1887.

10,555. **Improvements in electrical batteries.** Chaimsonovitz Prosper Elieson, 4, South-street, Finsbury, London.

AUGUST 13, 1857.

11,091. **Improvements in and connected with friction couplings governed by electricity.** John Smith Raworth and Henry Mannington Sayers, 46, Lincoln's-inn-fields, London, W.C.

AUGUST 29, 1887.

11,704. **An improvement in electrical insulators.** William Edwd. Langdon, John Crisp Fuller, and George Fuller, 33, Chancery-lane, London.

11,718. **Improvements in actuating mechanism for electrostatic generators.** Hermann Gläsar, 323, High Holborn, London, W.C.

AUGUST 30, 1887.

11,776. **New or improved system or apparatus for synchronizing electric telegraph instruments.** William Henry Beck, 115, Cannon-street, London, E C. (Gilbert Alfred Cassagnes, France.)

APRIL 19, 1888

5831. **Improvements in means or apparatus for lifting, lowering, and regulating the height of the elements in electric batteries.** Theodor Schönherr-Schöner, 2, East-parade, Leeds, Yorkshire.

APRIL 26, 1888.

6191. **A mode of preparing carbons for electric arc lighting.** Carl Anton Johannes Hugo Schroeder, 17, Althorpe-road, Upper Tooting, London, S.W.

MAY 29, 1888.

7851. **Improvements in switches for electric circuits.** William Phillips Thompson, 6, Lord-street, Liverpool. (George Westinghouse, Junior, United States.)

7853. **Improvements in or relating to storage batteries.** William Phillips Thompson, 6, Lord-street, Liverpool. (Charles David Paige Gibson, United States.)

SPECIFICATIONS PUBLISHED.

1887.

7865. **Dynamo-electric, &c., machines.** F. George. 8d.

9191. **Type printing telegraphs.** G. A. Scott. 1s. 6d.

9843. **Compensating electric measuring instruments for temperature.** W. T. Goolden and S. Evershed. 8d.

10,606. **Distributing, storing, &c., electric currents.** L. Gerard. 11d.

10,748. **Portable batteries for electric light.** A. Schanschieff. 8d.

12,645. **Electrical batteries for driving tramway vehicles.** W. D. Sandwelf. 6d.

13,954. **Electrical railways.** W. E. Irish. 11d.

1888.

1851A. **Sound conveying tube for telephones, &c.** J. Y. Johnson. (The Volta Graphophone Co.) 8d.

4524. **Portable galvanic batteries.** W. J. S. Barber Starkey. 8d.

6237. **Electric batteries.** A. Millar. 6d.

6416. **Galvanic elements.** L. and G. Hoppe. 4d.

6481. **Electrical transmission of power, &c.** H. H. Lake (Tesla.) 8d.

6502. **Generating and distributing electric currents, &c.** H. H. Lake. (Tesla.) 8d.

1881.

2272. **Secondary batteries.** J. W. Swan. 6d.—Fourth edition.

NOTES.

Copper from Japan.—The output of copper from mines in Japan is greatly increasing under foreign demands.

Technical Education.—It is hardly believed that the Government will proceed with the Technical Bill this Session.

The Cruto Lamp.—A French company has started a factory for manufacturing Cruto lamps in Paris. It is near Breguet's well-known works.

Brussels.—The lighting of the Northern Station at Brussels has been given to the Société Industrielle d'Electricité, the cost being 61,825 francs

Pullman Electric Cars. — Pullman's Palace Car Company are turning out a considerable number of cars fitted with electric motors for street tramway work.

Bingley Hall. — Messrs. Chamberlain and Hookham have received the contract, for the next three years, to light Bingley Hall, which is the largest in Birmingham, and is capable of containing 20,000 people.

Common as Blackberries.—Electric railways, says the *American Engineering and Mining Journal*, are becoming so common that the announcement of a new line or the adoption of electric locomotives scarcely attract attention.

Mill Lighting.—Another mill has been lighted in Bradford. Messrs. Dixon and Farrant, of Marshalls Mill, have had their works lighted by Mr. Wilson Hartnell. The dynamo is a Crompton 20-light machine, and the installation has been carried out in the usual careful and thorough manner that distinguishes Mr. Hartnell's work.

St. Catherine's Lighthouse.—In our issue of May 25 we referred to the installation of the electric light at this lighthouse, and our contemporary *The Engineer* has recently described the arrangement adopted. The lamp is a modified Serrin-Berjot, burning Sir James Douglas's fluted carbons. The three compound engines are by Messrs. Robey and Co., and the two dynamos are by De Meritens, of Paris.

Hospital Fete.—On Thursday in last week a fête, in commemoration of the silver wedding of the Prince and Princess of Wales, was held at the National Hospital for the Paralysed and Epileptic, at which the Princess Louise was present. The wards were prettily decorated with flowers and fairy lamps, and a variety of scientific and electrical apparatus was exhibited—among other things, the writing telegraph.

Newton Abbot.—Messrs. Vicary-Tanners, of Newton Abbot, are using their surplus engine-power for providing the electric light in their mills at Bradley. There are 82 incandescent lamps in the mill. The work has been carried out by Mr. Radcliff, who has also arranged to provide a temporary installation of electric light at the Winter Garden building at Torquay during the exhibition at the beginning of August.

Fire Brigade Alarms.—At Kidderminster it was notified that electric communication having been effected between the Town Hall and the members of the fire brigade, the use of the steam whistle as an alarm will be discontinued. We should be interested to know how many towns there are still in England which have not yet availed themselves of the use of electricity in connection with the fire brigade.

Printing by Electricity.—The San Francisco *Mining Scientific Press* is printed on a machine run by an electric-motor worked off the main of the Pacific Power Company. "This power," says the editor, "leaves nothing to be desired. It is steady, cheap, noiseless, odourless, free from dust, ashes and dirt, reliable, and 'altogether lovely.'" The motor employed is Prof. Keith's (of San Francisco) patent, and works also the passenger elevator for the offices.

Lambeth.—At the Vestry meeting, on July 5, a letter was received from the Assistant-Secretary of the Board of Trade, stating that all reference to the parish of Lambeth had been omitted from the proposed South Metropolitan Electric Lighting Order.—A notice was received from Messrs. Deacon, Gibson, and Medcalf that the London Electric Supply Corporation intended to apply for a provisional order for the supply of electricity for an area which would include the whole of the parish of Lambeth. A similar notice was received from the South Metropolitan Electric Supply Company.

The Microphone in War.—According to the French papers, the microphone was used during the manœuvres of the 17th Army Corps to detect the passage of bodies of troops in the neighbourhood of forts. From the experiments made, it appears that no difficulty was experienced in distinguishing between the various arms which passed the buried microphone, infantry, cavalry, artillery, and engineers all indicating their personality unmistakably. An attempt was made to count the number of men of each arm of the service, and we are told that out of 5,000 men only 340 were unaccounted for.

Continental Telegraphs.—Mr. Henniker Heaton, in the House of Commons last Monday asked the Postmaster-General whether an agreement had been made between France and England for conducting the telegraph service between the two countries independent of any private company, and whether he was prepared to state the nature of the agreement entered into and the rate per word of the cable messages which had been decided on. Mr. Raikes, in reply, stated he was not yet in a position, with a due regard to the public interest, to give any information on this subject. As soon as the negotiations have reached a point admitting of it, he will be glad to inform the House as to the arrangements contemplated.

Electrolytic Bleaching. — Messrs. Paterson and Cooper are busy with a considerable quantity of electrical plant for use in the Hermite process of electrolytic bleaching, used in treating paper pulp. A current of 1,200 amperes is used in the process, at a pressure varying with the number of vats employed. The meter for these large currents is a very peculiar and extremely simple one, illustrated by us a few weeks ago. The "coil" consists of a single solid bar of copper, about 1¼in. in diameter, closely embraced by an iron ring, which acts as magnet under the influence of the large current; the needle oscillates in a slot turned in the ends of this. The details of the process of bleaching are not yet made public, but are said to be very satisfactory.

Henley Regatta.—Quite one of the noticeable features at Henley Regatta this season was the little electric launch sent down by Messrs. Immisch and Co., which flitted about without apparent means of progress, and seemingly according to its own volition. The question of providing power for the launch has been boldly tackled by Messrs. Immisch, who have laid themselves out for providing charging stations at various points along the Thames. One of these stations

Digitized by Google

was in evidence at Henley. It consists of a large barge of 50 tons burden, fitted with an engine and a couple of dynamos, which was towed up the river by the electric launch. In the evening the station at Henley Regatta was brilliantly lighted by incandescents, and contributed its quota to the illuminations.

Old Style Lighting Revived.—Electric light contractors had better be looking around. We hear of several towns actually going back to oil for their public lighting. The town authorities of Erith, Kent, so we understand, have adopted a new pneumatic safety oil-lamp in lieu of gas, and a special exhibit of this lamp for public lighting is to be seen at the Glasgow Exhibition. The lamp burns 60 hours, and requires trimming only once a month, and costs 50s. a lamp per annum of 30 c.p.—gas of 14 c.p. costing 80s. There is nothing like competition for stirring up all the latent energies of our rivals, and what with regenerative and incandescent gas-burners and pneumatic oil-lamps they are indeed doing wonders. But we hardly suppose our electric light pioneers are going to be left behind through a little enthusiasm and flare up of the "old style" illuminants.

Quite Unforeseen.—The other day a pair of tom-tits went a long way towards producing a catastrophe, which no amount of foresight could have provided for. The grounds of the powder works at St. Medard, near Bordeaux, are lighted by arc lamps, and one of these has a resistance-box interpolated in the circuit, which is fixed to the lamp-post. This box had two holes in it, and a tom-tit, prospecting for a nesting place, decided in favour of the box, and proceeded to collect therein the usual straws and grasses wherein to rear its brood. Unfortunately, a high current heated the german silver wires forming the resistance coils to such an extent as to fire the nest, and then the box, which fell to the ground. Luckily the ground was damp, and the fire spread no further; but given dry weather and a light breeze, and many another home, besides that of the innocent causes of the fire, might have been destroyed.

London Bridge. — We understand that Mr. F. J. Beaumont and Mr. J. Kent, of the College of Electrical Engineering, Railway-approach, London Bridge, are starting a central station for that locality. The installation will present some novel features, in that the machinery for the central station is in connection with the "College." The pupils, after teaching, will be paid salaries, and employed in actual work, where possible, in installing and running what may be an extending central station. Arrangements are at present made for supplying 24 arc lamps in the various shops in the Railway-approach, and the neighbouring Turkish Bath, together some 100 or so incandescent lamps, and it is anticipated the demand will spread in that busy locality. The arc lamps are on a new design, and are exceedingly simple in construction. Practically, hardly anything is to be seen outside the globe except a small box or cap on the top, and the light given, moreover, is very steady.

Electric Lighting at Westminster.—In the House of Commons, on Monday, Sir H. Roscoe asked the First Commissioner of Works whether, in view of the serious deterioration of the stone fretwork of the interior of the Houses of Parliament, owing to the corrosive action of the products of combustion of gas, he would undertake to extend the system of electric lighting throughout the building, so as to avoid the evil consequences which attended the present system. Mr. Plunkett, in reply, said to extend the present system of electric lighting throughout the whole of both Houses of Parliament would involve a very considerable expenditure, not less than £40,000 for plant. It would, however, probably effect a considerable saving in the annual cost of lighting the palace. Before making any proposals upon the subject it would be necessary to consider whether some more economical way of obtaining the necessary current of electricity than that which we now use may be made available.

Poole.—The Corporation has been requesting tenders for the lighting of the borough from the 16th August to the 24th May, and the quay lamps all the year round. A tender was sent in for this purpose by the Poole Electric Light Company, whose letter stated that the firm of Messrs. Paris and Scott, of Norwich, electricians, had had a representative in the town who had prepared a plan, which was sent, showing the position in the town where the company would undertake to place incandescent lamps of 100 c.p. The cost would be £5 per annum for each 100 c.p. lamp, and £1 each for the smaller lamps, for which the present posts could be used. The Council would have to supply the lamps, which would cost about 25s. or 30s. each, and the company would provide the posts if they were allowed certain rights of erection. The charge would include lighting and extinguishing. The estimated cost for lighting the borough was £500 a year. The whole matter was referred to a committee.

The Brush Patents.—An important decision has been filed in the Federal court at Indianapolis, in the case of Charles F. Brush, of Cleveland, against John Owen and others, in which an infringement of patent was alleged by complainants, testing the validity of what is known as the Jenney system. The opinion, by Judge Gresham, is as follows:—1. The invention shown in the patent sued on was declared in patents 212,183 and 218,208; but in 212,183 the examiner held that Brush's claims were too broad. That decision was acquiesced in, and the invention which was there described, claimed, and rejected is now claimed in the patent sued on. The rejected invention was dedicated to the public by acquiescence in the ruling of the examiner, and cannot be claimed in a subsequent patent against others who meantime entered the field and used the rejected invention. 2. The patent in suit is limited to solenoids, and it does not include the common or electro-magnet, and thus construed the patent sued on is not infringed by the defendants. These, briefly, are the reasons for dismissing the bill for want of equity. The decision is regarded as unusually important, and the case is expected to go to the Supreme Court of the United States.

Fuel Testing Station.—A discussion has been going on in the engineering papers with reference to a proposed fuel testing station for London—a proposal in which it is likely that electrical engineers might be glad to co-operate. It has been mentioned as remarkable that sellers of coal take no trouble to find out the heat-generating power of the fuel that they are selling, nor do manufacturers on their part take much pains to find out what is the most that can theoretically be expected from the coal they buy, nor how far they obtain a good result in practice for their expenditure. A manufacturer ought to know exactly how many gallons of water could be evaporated by a ton of coal, and keep a record of his actual results. Tests of heat-producing qualities of coal would then be the recommendation by which a colliery owner or coal dealer would influence his customers, and

Digitized by Google

the users would be able to become acquainted with the latest improvements in the way of heat generators, smoke consumers, and furnace apparatus generally. Similar testing stations have been existent for some time on the Continent, and the proposal of a permanent institution of this kind in the neighbourhood of London seems to us worthy of all support.

Electricity and Fishing.—Prince Albert of Monaco, says the Paris correspondent of the *Daily Telegraph*, is now coming out in the character of a deep sea fisherman, but not for mere pastime. He is trawling in his yacht, the "Hirondelle," along the Atlantic coast, being intent on hauling in rare specimens of the finny tribe in the superior interests of science. A few years ago the distinguished yachtsman was engaged in observing the directions and velocity of the tides, and the results of his useful nautical researches were duly communicated to the Paris Academy of Sciences. The Prince has now informed M. Milne-Edwards of his present experiences, which will doubtless prove of great use to zoologists. A new and improved osier fishing-net has been supplied to the "Hirondelle," and this apparatus is made more efficient by means of an electric lamp, which will act as a bait and a snare to the fish, just as the candle does to the moth. The apparatus has been invented by Dr. Regnard, who has overcome the difficulties connected with supplying the electric lamp from a generator kept on board the yacht by simply storing the current in an iron case surmounted by a globe, and this is kept in its place at any depth, and is capable of resisting the pressure of immense volumes of water by means of an indiarubber air-balloon.

Barnet.—There seems to be some little delay in the arrangement for lighting Barnet, the Board having originally decided on 16-candle lamps, and Mr. Joel having made an agreement with them on that basis; but subsequently it was suggested that 16-candle lamps were not the best form of electric lighting for street purposes, and modifications were put forward. At the last meeting of the Board the following motion was made: "That this Board is willing to adopt 32-c.p. incandescent lamps in place of the 16-candle lamps mentioned in the contract submitted, at a price to be agreed between this Board and Mr. Joel." Six of the members voted for the motion, three against, so that it was carried. We have very carefully read a full report of the discussion upon the subject, and we think the whole arrangement is still in a very unsatisfactory condition, and there is no doubt that the remark of Mr. Tyron is not very far from correct. He asked what proof was there that in a short time they may not be told that 50-candle lamps were better than 32, just as they were now told that the latter were better than 16. The reply to this was that 50 must be better than 32, and 100 would be better still. It is a matter of judgment. Our opinion upon this whole matter is that incandescent lamps are not exactly suited for street lighting. The great argument in favour of the adoption of the electric light, states the report, is that the town is going to save money. This may be an absolute fact, but we doubt if much money is going to be gained by the supply of seventy-one lamps, unless this work for the Local Board proves to be only a peg upon which to hang the much larger work of lighting the houses of Barnet.

The Brush Company's Excursion.—The eighth annual excursion and dinner of the employés of the Anglo-American Brush Electric Light Corporation came off with great *éclat* on Saturday, July 7th. The party, numbering 146, left Liverpool-street (per Great Eastern Railway) about 7 o'clock in the morning, and reached the pretty seaside resort of Clacton-on-Sea at 10:42 a.m. The whole then entered with zest and hilarity into the full enjoyment of the scene, boating and bathing being freely indulged in, and all making the best of their time. At 1 o'clock the party adjourned to the Osborne Hotel, and partook of a splendid spread prepared by the genial host. The viands reflected greatly to the credit of the worthy caterer, and the whole were cleared with electric despatch. When the cloth was removed, the chair was taken by E. Garcke, Esq., secretary of the Corporation, who proposed the first toast, "The Queen and Royal Family." P. Sellon, Esq., gave the toast, "The corporation," and in a very interesting speech dwelt upon the unity which existed between employers and employés. Toast, "The Staff," was given by Mr. J. Evans, who referred to the "bond of unity" which has ever existed between them, and further expressed his belief that these annual gatherings did much to foster a better feeling amongst all classes. Mr. Fells, a member of the honorary staff, very ably and suitably replied in sympathetic terms. G. C. Sillar, Esq., the esteemed works manager, expressed in glowing terms his great pleasure in being present. There were also present Messrs. Mordey, Jackson, and Paterson, members of the hon. staff. Songs were well rendered during the proceedings by Mr. J. Fone, J. Brady, Mr. Ashton, who with much credit sung the "Forge," and their old friend, Mr. Favier, who in good style sung "The Four Jolly Smiths," amid cheers and enthusiastic encores. The party arrived back in London at 10 p.m. all safe and in good order, highly delighted with their seaside trip.

Electric Night Signals for Use at Sea.—The system of signals by incandescent electric lights, as recently adopted in the German and Italian navies, was exhibited by Lieutenant W. H. Beehler, United States Navy, on board the United States steamer "Atlanta," at Annapolis, recently, during the graduating exercises. The electric lamps are used in three lanterns, 12ft. apart, hoisted at the masthead, and the lights are displayed by means of a switch-box to open and close circuit through the combination of lights to make the desired signal. The lamps are arranged in pairs of one red and one white Edison lamp. Each of the three lanterns contains a pair of lamps, and no two lamps in the same lantern are displayed at the same time. The switch-box is a brass cylinder five inches in diameter and two inches high. Its upper surface is a dial with fourteen discs, ¼in. in diameter. These discs are made of pieces of red and white glass arranged to show the same combination of signal lights displayed in the lanterns aloft. It has an index, and the knob in the centre serves as a key, which, when raised, closes the circuit through the lamps aloft, corresponding to the combination covered by the index on the dial. When this knob is depressed, the lights aloft are immediately extinguished. The box has terminals to the dynamo machine, and six wires with a common return wire to the Edison lamps. It also has a receptacle for a small Edison lamp in the box to illuminate the red and white glass discs on the dial to be visible at night. The fourteen combinations possible are as follows: White, 1. Red, 2. White—red, 3. Red—white, 4. White—white, 5. Red—red, 6. White—red—red, 7. Red—white—white, 8. White—white—red, 9. Red—red—white, 0. White—red—white, correct. Red—white

Digitized by Google

—red—preparatory. White—white—white—answering. Red—red—red, interrogatory. The system is readily adapted for the general naval signal-book and telegraphic dictionary like the flag numerals of the day signals. In order to make any signal, the message is first sought in the signal-book and the number corresponding thereto is then signalled.

Accumulators for Tramways.—"When this company," writes the president of the Julien Traction Company, "began to make storage batteries in this country some two years ago, it was compelled to adopt the rather crude methods then and now in use in England and on the Continent, and still in use by every other company but this. We refer chiefly to the fact that the battery had to be entirely hand-made; but we have recently invented machinery (fully covered by United States patents), more especially our mechanical filler, whereby two persons, with one machine, can make more battery in a day than 50 persons could hitherto make. This has enabled us to reduce the cost of the battery to at least one-half of what it has hitherto been. It has, furthermore, made the manufacture of the battery so simple that every large road can repair and remake its batteries in a small space and without any mechanical skill. We have removed the mysteries that have hitherto surrounded the manufacture of the storage battery, and made its production as simple as that of almost any article of commerce. The ideal method of traction," he further says, "is a car propelled by self-contained energy. The cable, overhead wire, and the conduit system will never satisfy the spirit of human progress. That spirit can only be satisfied by each car being an independent unit and self-propelled. That such a car can be practically run and carry passengers by the aid of storage batteries no longer admits of any doubt in view of our experience with the car on Fourth-avenue, in St. Louis, and in Brussels. The only obstacle, therefore, that seemed to be in the way, or, rather, the only question or doubt, was as to its expense; and that expense was owing chiefly to the high price of the storage battery; but even this obstacle has been overcome by the methods lately invented by this company for manufacturing the storage battery cheaply. Up to a very recent date, the amount of storage battery required for a car cost more than the horses. This company is now prepared to replace the horses by storage batteries for a price much less than the cost of the horses. This fact alone, as every engineer will understand, removes the last remaining obstacle to the universal adoption of the storage battery system."

Resistance at Low Temperatures.—Some interesting researches have just been made into the diminution of electrical resistance of copper at a very low temperature, by M. Wroblewski, with reference to the statement by Clausius that the resistance of chemically pure copper should be proportional to their absolute temperature. The result of his experiments go to show that the electrical resistance decreases not only in proportion as the temperature is lowered, but even more quickly than this, and that a point at which the electrical resistance will be absolutely done away with can be obtained by means already known. It is certainly astonishing to think that a wire which will at ordinary temperatures carry only 1 or 2 amperes at a low temperature could be made to carry, say, 100 amperes. The means which M. Wroblewski took advantage of for producing an extremely low temperature was that of evaporating hydrogen at the temperature of its solidification, by which a rapid and intense abstraction of heat is produced. The coils employed were wound of double silk-covered copper wire, having a diameter of 0·025 millimetre, and guaranteed 98 per cent. conductivity. The coils had a resistance of between 3 and 20 Siemen's units at ordinary temperatures. These had to be plunged in liquified oxygen and nitrogen, which M. Wroblewski found were among the most perfect electric insulators. The resistances of the coils were then measured by the Wheatstone-Kirchoff method at various temperatures—namely, the temperature of boiling water, ordinary temperature, the temperature of melting ice, the temperature of boiling ethylene at atmospheric pressure (– 103deg. Cent.); the critical temperature of nitrogen (– 146deg. Cent.); the temperature of boiling nitrogen under atmospheric pressure (– 193deg. Cent.); and a temperature nearly that of the solidification of nitrogen (– 200deg. Cent. to – 202deg. Cent.). The results are given in the following table, in which T is the temperature, R the resistance in Siemens units, and a the co-efficient of variation of resistance between two consecutive temperatures:—

Coil I.			Coil II.		
T. Deg. C.	R.	a.	T. Deg. C.	R.	a.
+ 100	5·174		+ 23·75	19·251	
+ 21·4	3·934	0·004365	+ 23·75	17·559	0·004057
– 21·4	3·614	0·004136	– 103	9·848	0·004263
– 103	2·073	0·00414	– 146	6·749	0·004104
– 146	1·360	0·004588	– 193	2·731	0·004869
– 193	0·580	0·004592	– 201	1·651	0·007638
– 200	0·414	0·006562			

It will be seen from these figures that the resistance approaches zero more quickly than the temperature approaches – 274deg. Cent.

Conversazione.—The President of the Society of Telegraph-Engineers and Electricians and Mrs. Graves held a conversazione in the galleries of the Royal Institute of Painters in Water Colours on Tuesday evening, the 10th inst., which was very numerously attended, it being estimated that as many as 600 persons were present. The Band of the Coldstream Guards, under the conductorship of Mr. C. Thomas, played selections of music, and added greatly to the enjoyment of the evening. The pictures afforded pleasant material for conversation, though it is to be regretted that they are still exposed to the deleterious effects of gas. Altogether, the evening was a very pleasant one. The following are a few of the names of those present that occur to us:—*Visitors:* Sir Edward and Lady Birkbeck, Capt. E. M. Shaw, C.B., M. Fontaine, Prof. Groves, F.R.S., Rev. J. Macnaught, Prof. Frankland, F.R.S., Geo. Berkeley, Prof. Vernon-Harcourt, Capt. W. J. L. Wharton, R.N., T. A. Highton, L. W. Courtenay, H. Perigal, Sir Philip Magnus, Don Arturo de Marcoartu, Prof. W. Hudson, Dr. Plimpton, Sir Arthur Blackwood, K.C.B., Capt. Adams, C. Hawksly, G. J. Symons, F.R.S., J. Wimshurst, Dr. Tison, Wolfe Barry, Dr. Radcliffe. *Members*: Sir W. Gurdon, Sir David Salomons, Bart., Sir Henry Mance, C.T.E., Sir Douglas Galton, K.C.B., F.R.S., Prof. S. P. Thompson, F.R.A.S., Prof. G. C. Forster, F.R.S., Prof. Forbes, F.R.S., Prof. W. G. Adams, F.R.S., Prof. J. Perry, F.R.S., Prof. W. E. Ayrton, F.R.S., Prof. D. E. Hughes, F.R.S., Alexander Siemens, W. Crookes, F.R.S. W. H. Preece, F.R.S., Capt. H. Sankey, R.E., Col. Hamilton, R.E., Dr. J. H. Gladstone, F.R.S., Bernard Drake, Augustus Stroh, E. March Webb, Major C. F. C. Beresford, R.E., F. H. Varley, Louis Lœffler, J. N. Shoolbred, J.

Patey, C.B., Capt. C. A. M'Evoy, Major-Gen. E. R. Festing, F.R.S., Dr. J. Hopkinson, F.R.S., Shelford Bidwell, F.R.S., Major-Gen. C. E. Webber, C.B., R. P. Sellon, C. E. Spagnoletti, W. H. Snell, W. B. Esson, F. Higgins, Dr. Walmsley, Dr. Steet, Captain G. W. Addison, R.E., F. Despointes, J. Farquharson, Charles Gerhardi, Dr. Oback, R. Waring (of Pittsburgh, U.S.A.), R. E. Crompton, R. K. Gray, Dr. G. A. Fleming, M.D.

Bradford.—The Bradford Corporation, in view of their scheme for erecting a central generating station in Bolton-road, for providing a regular supply of electric lighting and power for Kirkgate, Market-street, and places in the immediate vicinity, have recently issued a circular to occupiers of business premises in the central portion of the borough inquiring whether such occupiers would be disposed to take a supply of the current regularly for a stated period, suggested as three years. So far there has been a fair response to the inquiry, though it is somewhat early to enable the Corporation to say to what extent the experiment is likely to succeed. In addition to places of business, the free library, the markets, and other public buildings in the neighbourhood of Kirkgate are to be provided with electric light. It is proposed to make the supply continuous, except between 1 a.m. and 5 a.m., unless otherwise arranged. With respect to price, the Corporation have determined to adopt an alternative system of charge for incandescent lamps—namely (1), 5d. per unit, the Corporation to supply meters, if desired, at a rental of 10 per cent. on the cost; (2) by an annual charge of 20s. per lamp of 16 c.p., irrespective of the actual hours of lighting. The charge for the supply to arc lamps is to vary with the illuminating power of the lamp as required by the consumer at the rate of 5d. per unit. Ten units with incandescent lamps of 16 c.p. produce an amount of illumination equal to about 1,000 cubic feet of 15-candle gas. It is pointed out that the price is unavoidably higher at first than gas at its present low rate in Bradford. But against this are to be set the advantages which the electric light has over gas. The Corporation propose to carry the supply up to the buildings, the internal fittings being provided by the consumer.—At the meeting of the Town Council on Tuesday the Gas Supply Committee recommended the appointment of Mr. Sydney Baynes as clerk of works in connection with the electricity works, at a salary of £150 per annum, and then came a question æsthetical. Mr. Bottomley asked whether it was the intention of the committee to erect a brick chimney at the electrical works instead of a stone one. He was of opinion that a brick chimney would be very unsightly, and the Corporation had already prohibited the erection of a brick chimney by a certain firm in Bradford. Alderman F Priestman (chairman of the committee) said it was quite true that the committee were about to erect a brick chimney, and he thought they would be able to show how beautiful a brick chimney could be made to look. He believed that the handsomest chimney in the district was of brick, and undoubtedly for a mill a brick chimney was better in point of construction than a stone one, and he did not know why it should be thought that a uniform grey stone was necessarily the handsomest kind of structure which could be adopted. Eventually, if the electric installation should prove successful, the roof of the works would be raised, and the chimney would be built round for a considerable height, and only a portion of the chimney would be exposed to view. It was better to build the chimney as proposed rather than build an expensive stone chimney.

Nominal Horse-Power.—There are few technical terms which have so little real meaning as that represented by the letters N.H.P. It is not possible for any definite value to ever be assigned to this term independent of steam pressure, but a greater accuracy might easily be obtained in the relative value of the term as between engines of different makers. The following attempt, which has been made in the *Practical Engineer*, to roughly standardise this expression for commercial usage may prove useful :—"Nominal horse-power" is a term used to give an approximate idea of the commercial value of an engine, but has no fixed relation to either the actual or indicated horse-power exerted, but is essentially a conventional term, and is frequently determined simply from the size of the cylinders, leaving out of the question such variable factors as steam pressure, speed, &c. As no universal rule has ever been adopted, and as each maker has his own method of computation, the greatest differences in the calculated n.h.p.'s of different engines of the same power may often be found. In marine practice a common rule for compound engines is to allow 30 circular inches of cylinder per n.h.p. That is, $\text{N.H.P.} = \frac{d^2 + D^2}{30}$, where d = diameter high-pressure cylinder, and D = diameter low-pressure cylinder. If the other factors affecting the power developed depended on the diameter of the cylinder, this rule would be a fair one. But it is evidently misleading as it stands, for two engines may have the same cylinder diameter, but very different cylinder lengths. By introducing another factor, the piston speed, we might get a closer approximation; but the piston speed depends upon the supply of steam, and, therefore, if we want a close approximation we must base our estimate upon the boiler capacity, as well as upon that of the engine. A modern writer has given the following rule for finding the "estimated" h.p. of compound marine engines :—$\text{E.H.P.} = \frac{D^2 \times \sqrt{p} \times R \times S}{8{,}500}$, where D = diameter low-pressure cylinder, p = boiler pressure, R = number of revolutions per minute, S = stroke of piston in feet. This formula is evidently nothing but a means of approximating the indicated h.p. of the engine; but it certainly is a much more reliable criterion of the commercial value of the engine than the n.h.p. calculated from the cylinder diameter would have been. The need of some universal formula which will give an idea of the commercial value, and also of the real capability of the type of engine, is becoming more pressing now that the triple expansion engine, with its high pressure and speed, is so rapidly coming into prominence. Also the fact that certain charges made against ships are based upon the registered n.h.p. of their engines makes some means of determining this function a necessity. A rule that seems to meet all the requirements was proposed by Mr. Macfarlane Gray, and is as follows :—$\text{N.H.P.} = \frac{1}{2}\left(\frac{D^2 \times S}{630} + F\right)$, where D = diameter low-pressure cylinder in inches, S = stroke of piston in inches, F = total width of fire-grate in inches, 630 = a constant. It is true that the result obtained by the use of this formula is the n.h.p. of the boiler and engine combined; but they are so mutually dependent that no accurate idea of the value of the engine can be obtained without considering the capability of the boiler.

ELEMENTARY TESTING SUITABLE FOR ELECTRIC LIGHTING SYSTEMS.

BY THOMAS GRAY, B.SC., F.R.S.E.

[*All rights reserved.*]

(Continued from page 583.)

THOMSON'S INSTRUMENTS.

Reflecting Galvanometers.—The most important peculiarity in the reflecting galvanometers introduced by Sir William Thomson is the lightness of the suspended part. The magnetic needles are made very small, and thus allow the wire forming the coils to be disposed round them in a very effective manner. These features are of great importance when sensibility and rapidity of action are required. Sensibility implies a small controlling force compared with the deflecting force produced by unit current passing the coil, and rapidity of action requires the period of oscillation to be short, the rate of subsidence of the oscillations great, and the zero of deflection definite. In Thomson's instruments the moving system is suspended by a single fibre of silk, and the rigidity of this fibre is so small as to be negligible in most cases. Hence, in accordance with the principles already discussed, the controlling force depends almost wholly on the strength of the magnetic field surrounding the needles and on the nature of the needle system. Take, for example, a single needle of magnetic moment, m, and suppose the moment of inertia of the moving system round its axis of suspension to be μ and the intensity of the controlling field to be H. Then the period of oscillation, P, of the needle, or the time which it takes to make a complete double swing, will be

$$P = 2\pi \sqrt{\frac{\mu}{m\,H}}.$$

Now, for sensibility, H must be small, and by the construction of the instrument m is necessarily small, hence μ must be small also. If the moving system consisted of nothing but the magnetic needle, μ would depend on its mass and its shape; being directly proportioned to the mass multiplied by the square of the length when the needle is moderately long compared with its thickness. The value of m, on the other hand, is for all ordinary needles very nearly in simple proportion to the mass of the needle; the length having very little effect unless the transverse dimensions of the needle is a considerable fraction of its length. From this it is clear that the fraction μ/m can be, within certain limits, made small by reducing the length of the needle. This is accomplished in the Thomson needle by using four short flat needles, placed edge to edge a little distance apart, instead of one four times the length. In the actual case, the moving system consists, at the least, of the magnetic needles and a mirror to indicate, by the reflection of a beam of light, the deflection of the needles. The problem is thus complicated by the fact that μ consists of two parts – the moment of inertia of the needles and that of the mirror. The effect of the mirror is made as little as possible by using a small size and constructing them of exceedingly thin glass. The mirrors used are about one centimetre in diameter, and weigh only about the hundredth part of a gramme. There are two kinds of these galvanometers in common use, known as "dead-beat," and "astatic" mirror-galvanometers respectively. In the "dead-beat" form, the moving system consists of one set of needles, which are attached to the back of the mirror, and give the simple system above referred to. The astatic form contains two sets of needles, and requires besides the needles and mirror, a frame to carry them. In the best form of these instruments this frame consists simply of a straight vertical wire of aluminium, just thick enough to bear moderately rough usage without becoming bent. The increase of μ due to this wire is very slight.

"Dead-beat" Galvanometer.—The coil of this galvanometer consists of a single bobbin of well insulated copper wire, circular in front or back elevation, and of the form shown in Fig. 28 in longitudinal section. The number of turns of wire on the bobbin and the size of the wire used depend on the purpose for which the instrument is intended, but in all cases the diameter of the wire should be varied from the centre to the outside of the coil in such a way that at any layer it is nearly proportional to the diameter of the central ring of that layer. This method of winding is adopted in order that when a current is passed through the coil, the rate of fall of potential along the wire forming the coil is at any point proportional to the turning couple exercised on the needle by unit length of the wire situated at that point. This arrangement of the wire gives the greatest turning couple on the needle for any E.M.F. on the terminals of the coil, and hence for general purposes, and in galvanometers specified to have a certain resistance, it should always be, as nearly as practicable, adhered to. In some special cases where the resistance of the instrument is a matter of indifference, but the number of turns in the coil important, better results are obtained by using wire one uniform thickness throughout. Such cases will be considered in their proper place. The proper form for the central line of the cross section of any layer of wire was shown by Thomson to be expressed by the equation—

$$x^2 = (a^2\,y)^{\frac{2}{3}} - y^2$$

where x is measured from the centre along the axis of the coil, and y is any ordinate measured from and at right angles to that axis, and a is a constant for each layer which is equal to the value of of y when x is zero. The diameter

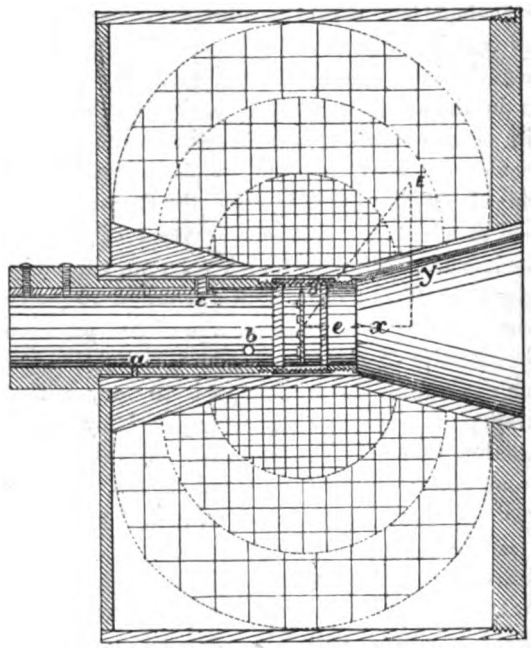

FIG. 28.

of the wire should be proportional to a to obtain the maximum deflection for any E.M.F. on the terminals of the coil. The forms of the layers, as given by the above equation, are shown by the dotted lines in Fig. 28. The usual practice is, as indicated by the squares in the figure, to wind on several layers of each of three or four different thicknesses of wire, the wires being so chosen that the aggregate resistance will be equal to that specified for the coil. The shape of the outside of each of these sections of the coil is made as nearly as possible the theoretical figure; but very close accuracy is difficult, and is not important. The proof of the above equation may be easily obtained as follows:— Let E be the cross section of any turn of the coil, x and y its co-ordinates. Then the axial component of the field, or the intensity of the field in the direction of the axis of the coil, produced by unit length of wire at E, through which unit current is flowing is—

$$\frac{y}{(x^2+y^2)^{\frac{3}{2}}} \quad \ldots\ldots \quad (1).$$

Now, the layer of wire which produces per unit length the same axial component, must have $y/(x^2+y^2)^{\frac{3}{2}}$, equal to a constant, equal to $1/a^2$, let us suppose. Then we may write:—

$$1/a^2 = \frac{y}{(x^2+y^2)^{\frac{3}{2}}} \quad \ldots\ldots \quad (2)$$

Digitized by Google

$$\text{or, } x^2 + y^2 = (a^2 y)^{\frac{2}{3}};$$

$$\therefore\ x^2 = (a^2 y)^{\frac{2}{3}} - y^2.$$

We thus see that Thomson's equation expresses the form of a layer of wire, each part of which is equally effective. We have still to consider the effect of passing from one layer to the next. Take the central ring of any one layer, and we have, putting $x = 0$ in equation (1), for the effect per unit length of the wire the square of the reciprocal of the radius. Hence, the rate of fall of potential along the wire must be proportional to this quantity, or the section of the wire must be as the square of the radius of the central ring—that is, the diameter of the wire must be as that radius. The graduation of the thickness of the wire, in the manner here indicated, has considerable advantage for galvanometers which are intended for general laboratory work, and especially for low resistance instruments intended for use in the circuit of thermo-electric junctions of almost zero resistance. For galvanometers which are intended mainly for use in the measurement of the leakage current through the insulation of telegraph or electric light circuits, the number of turns on the coil is the chief element to be considered. The resistance of the circuit being very great compared with that of the galvanometer, it is generally better to use wire of uniform thickness throughout.

The axial component, in C.G.S. units, of the magnetic field produced by one of these coils when an ampere of current is flowing through it varies between 70 times the square root of the resistance in ohms for a coil of about 5,000 ohms resistance, to 140 times the square root of the resistance in ohms for coils of about one ohm resistance.

The mirror and needles of this galvanometer are suspended in the centre of the bobbin inside a small cylindrical cell formed at the end of a plug, which fits the central tube of the bobbin. The cell is formed by a thin brass tube, *d*, screwed in the inside so as to fit a corresponding thread cut on the end of the plug, a glass end fitted into the plug, and a lens, *e*, fitted into a brass frame which screws into the tube, *d*. The mirror is ⊔ shaped, nearly fits the tube, *d*, round its circular edge, and is suspended from the top of *d* by a short fibre of silk attached to the middle of its straight edge. The width of the cell can be varied by screwing the plug and the lens frame more or less into the tube *d* until the friction and inertia of the confined air in this cell so damps the vibrations of the mirror as to make it come almost instantly to rest when deflected. The plug is held fairly and securely in position, in the bobbin, by means of three fixed feet, two of which are shown at *a* and *b*, and a spring foot, *c*, vertically over the centre of the triangle formed by the other three. For use in the Wheatstone bridge, and for other similar purposes, where a quick acting and a sensitive galvanoscope is wanted, this is the most suitable form of galvanometer at present available. The form of the complete apparatus with lamp and scale as now manufactured, under Sir William Thomson's own supervision, by James White, of Glasgow, is shown in Fig. 29. In this figure the complete apparatus for the Wheatstone bridge test is shown. A is a battery of three small secondary cells, B is a scale of half millimetres and fifty centimetres long, C is the glass funnel of a paraffin oil lamp placed behind the scale, D is a dial box of resistance coils, with two auxiliary sets of coils between I and J and J and K, E is the galvanometer, F is a bobbin of wire which is being tested, G and H are two reversing keys. The terminals of the battery, A, are connected to the front terminals of the key H, and the back terminals of that key are connected to the terminals I and K of the box. The terminals J and L of the box are connected to the front terminals of the key G, while the back terminals of that key are connected to the two terminals of the galvanometer. The ends of the bobbin, F, are put in the terminal screws L and K. By this arrangement it will be seen that either the direction of the current through the box or the direction of the current through the galvanometer can be changed independently of each other. For the sake of clearness, the wires are shown in the figure passing directly to their respective terminals, but in actual practice the two battery electrodes, from the battery to the key, and from the key to the box, should be arranged so close to each other that the current through them does not deflect the galvanometer needle.

An objection to this galvanometer in the form here shown is, for some purposes, its comparative want of portability, because of the necessity for a separate scale and lamp, and it is sometimes difficult to obtain a sufficiently steady table to use it on. A very portable form can be made, however, by dispensing with the lamp altogether and using a plane mirror, the reflection of a short scale in which can be viewed either directly or by means of a small telescope. The effect of vibration on the mirror can be almost completely annulled by suspending the coil by means of rubber bands from any convenient support, or from a frame supplied with it.

For the estimation of the relative values of currents by the deflection of the galvanometer needle, the suspension of the mirror and needle by means of a very short fibre, as is the case in the instrument above described, is unsuitable. The rigidity of so short a length of even single silk fibre is not generally negligible in comparison with the other forces involved, and hence the imperfect elasticity of the fibre causes the deflection to gradually increase with time, thus rendering great accuracy impossible. For many purposes, however, the very light moving system, which is used in these instruments, is such an advantage that it is advisable to arrange the coil in two halves, and suspend the mirror and attached needles by a long fibre passing down between the coils. The arrangement for obtaining the cell for the mirror have then to be modified, and generally the action is not quite so perfectly "dead-beat," but still the rate of subsidence is much greater than it is in most forms of the "astatic" galvanometer, which instrument we will now describe.

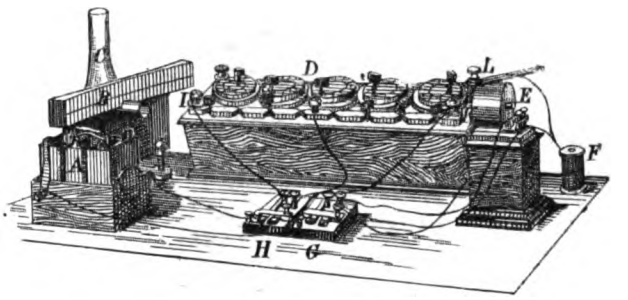

FIG. 29.

Astatic Galvanometer.—In this instrument the double-needle system as introduced by Nobili is applied to the small needles and light mirror used in the "dead-beat" instrument. The needle system consists of two sets of small flat magnets, each arranged to form a disc-shaped needle of about one centimetre diameter. One of these sets of needles is generally carried on the back of the mirror, and the two sets are held in a fixed position relatively to each other by means of a suitable frame. The frame is always made as light as possible, but has different forms according to the arrangement of the instrument. In an early form of the instrument, which, however, is seldom now adopted, there was only one coil, and it was wound on a single bobbbin—was, in fact, the same as that described above and illustrated in Fig. 28. The needles were in this case carried at the middle of the horizontal bars of a rectangular frame of aluminium wire, one of the horizontal bars of which passed along the axis of the coil, and the other parallel to it over the top of the coil. One set of needles was thus in the middle of the axis of the coil and the other set vertically above it, but outside the coil. The effect of the current through the coil was to deflect both needles in the same direction, but the outside set experienced much less force than the central set. A similar arrangement was sometimes adopted for carrying the needles when two coils were used, each set being carried on the centre of a horizontal bar passing through the centre of two separate coils placed vertically over each other. In this case the needles of each set were sometimes made of round bars, about one centimetre long and one-twentieth of a centimetre in diameter, arranged at the four horizontal edges of a cube of cork or pith. The mirror was in all these cases carried on a vertical stem projecting up from the centre of

Digitized by Google

the frame above the coils. This arrangement, although convenient, and because of the comparative simplicity of the coils, cheap, added very greatly to the moment of inertia of the moving system, and thus took away very much of the advantage of the small needles and mirrors. In almost all the instruments now produced by the best makers the coils are made in two halves, and the needle system is mounted on a vertical rod of thin aluminium wire which passes down a vertical slot formed between the coils. A form of the instrument designed by the present writer, and which differs only in some details of its framework from the ordinary forms, is illustrated by means of a front view in Fig. 30. The object is to obtain an instrument which has a very high insulation from earth, which provides the means of readily varying the rate of subsidence of the oscillation of the needles, which is readily accessible in all its parts, and which can be used without a case. In this instrument the coils, *g k*, are made in two halves, and are either hinged or are held by a species of bayonet joint in a vertical plate, *e*, of brass, or, if the instrument is to be used for transient currents, of some good insulating material, such as vulcanite, or white marble soaked in paraffin. In this latter case the coils are also made of insulating material.

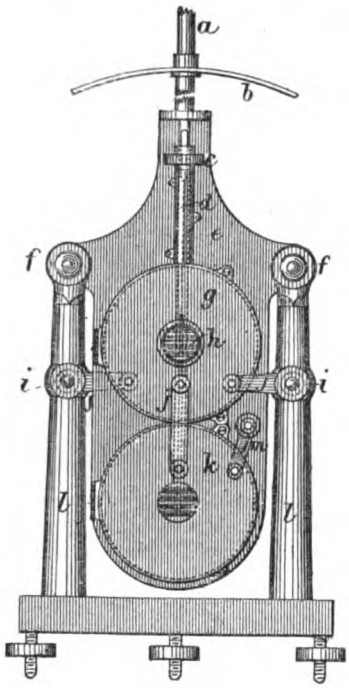

FIG. 30.

It may be interesting to notice here that recent experiments conducted at the writer's suggestion by Mr. Thomas Shields, M.A., in the physical laboratory of Glasgow University, have shown that white marble is an excellent insulator, and that when dried and soaked for a short time in melted paraffin it is little affected by moisture, and is extremely easily worked by ordinary instrument makers' tools. This material is cheap, and is much to be preferred to vulcanite for many purposes. The plate *e* is supported by two insulating pillars, *l l*, being clamped to two metal pieces, *f f*, fixed to the tops of the pillars. The terminals, *i i*, of the instrument are also fixed to these pillars, a little below the metal top when the plate, *e*, is of metal ; they may form a part of the metal pieces, *f*, when the plate is of insulating material. Each half of the coils is provided with two terminals, and they are joined in series or parallel, as may be desired, by means of straps, *j*, the connection from the front to the back pair of half coils being made by means of a rod, *m*, fixed to the plate, *e*, and fitted with a small terminal screw at each end. In the form here shown the mirror, *h*, is in the centre of the top coil, and carries one set of needles on its back, while the other set of needles is carried by a vertical wire fixed to the top set of needles, and is arranged to be in the centre of the lower coil when the mirror is in the centre of the upper one. A somewhat better arrangement of the coils round the needles can be made when the vertical rod is continued up through the top coil, and the mirror is placed in a separate cell with a plane glass front fixed in the plate, *e*, at a point a little above the coils. The needles and mirror are suspended by a silk fibre, which passes up through a slot in the plate, covered along the upper portion by a tube, *d*, the front portion of which can be removed for suspension purposes should the fibre break. A nut, *c*, working on a screwed rod, serves to raise or lower the needles, which can thus be readily lowered so as to rest at the bottom when the instrument is carried about. The "damping" effect on the needle is produced by means of plugs with glass ends (not shown in the figure), which slide into the central tube of the coil bobbins. By adjusting the distance of the glass ends from the needle, any desired amount of "damping" can be obtained. A controlling magnet, *b*, is provided, mounted on a vertical rod, *a*, above the suspension screw, and can be raised or lowered, or turned in azimuth so as to produce the amount and direction of controlling force desired. When a specially long suspension fibre is desired, which is advisable when very high sensibility is aimed at, the rod, *a*, on which the controlling magnet is mounted may be made a tube, and the suspension fittings placed at the top of it. It is convenient in this case to attach the suspension to the mirror and needle rod by means of a hook, so that it can be readily unhooked, as this simplifies the attachment of a new fibre.

Astatic galvanometers are generally made of high resistance and used for the measurement of very small currents, such as the leakage through the insulation of a telegraph line or cable, or from the leads of an electric light circuit to earth. It is not uncommon, when this leakage current is very small, for the controlling force due to the magnetic field to be so small that the rigidity of the suspending fibre plays an important part in limiting the possible sensibility of the instrument, and also the accuracy of its indications.

The torsional rigidity of a silk fibre averages about ·0015 C.G.S. units per centimetre of its length, and hence in a suspension five centimetres long the rigidity will be about ·0003 of the same units. Now, let C be the current flowing through the coils of the galvanometer, K a constant depending on the coils, I and I^1 the intensity of the magnetic field at the upper and lower needles respectively, m and m^1 the magnetic moment of these needles, τ the torsional rigidity of the suspension fibre, and θ the deflection produced by the current C. Then we have

$$C = K\left(\frac{Im - I^1 m^1}{m + m^1}\tan\theta + \frac{\tau\theta}{(m+m^1)\cos\theta}\right).$$

When the needle system is perfectly astatic, $m = m^1$, and the equation reduces to

$$C = K\left(\frac{I - I^1}{2}\tan\theta + \frac{\tau\theta}{2m\cos\theta}\right);$$

and for the small deflections used with these instruments may be written $C = \frac{1}{2} K\theta(I - I^1 + \tau)$.

From this equation, we see that the fibre becomes an important element when τ/m is not small compared with $I - I^1$. In very sensitive instruments $I - I^1$ varies from about ·01 to ·001, and in the Thomson form of needle m is approximately unity. Hence, the effect of the fibre, relatively to that of the magnetic field in controlling the deflection, may be about in the ratio of ·0003 to ·005; or, 1 to 17. This effect of the fibre would be of no importance were it not for the fact that its elasticity is very imperfect, in consequence of which the deflection apparently gradually increases, thus rendering it difficult to tell exactly what the true deflection is. We may assume, therefore, that for the Thomson astatic instrument the value of $I - I^1$ should not be made less than ·01. This is equivalent to saying that the current required to produce a motion of one-half millimetre division of the spot of light reflected from the mirror on a scale one meter distant from it should not be less than 10^{-10} amperes for a galvanometer of about 5,000 ohms resistance. When higher sensibility than this is required the fibre should be made much longer, and if possible m should be made larger. Other forms of galvanometer, designed by the present writer with the view of pushing the reliable sensibility of a galvanometer considerably higher, and which have been fairly successful for that purpose, will be described further on.

(To be continued.)

PETER ROBINSON'S.

London is so big that an installation of the nature of a central station, and quite as large in itself as the lighting arrangements of many an American town, can be hidden away in one corner of its streets. The installation at the well-known costumiers, Messrs. Peter Robinson and Co., is one of the largest combined arc and incandescent installations at present running in London, and almost equal in its size to the Italian Exhibition, comprising, as it does, 80 arc lamps and 400 incandescent, which will shortly be increased to 700 in number. The installation, in a smaller form, has been running for some eighteen months or so, and was carried out under the superintendence of Mr. Ernest G. Craven, A.M.I.C.E., 22, Great George-street, Westminster; it has since been added to from time to time, and now makes one of the most interesting private installations in London. In order to get entirely rid of noise, dirt, and vibration, the excavations for the engine-room were taken down two floors below the ground. Going down into this subterranean locality, under the courteous guidance of Mr. C. Wenham, who has the whole electric department under his control, we come upon the familiar whirl and rush of the machinery.

A fine and spacious engine-room is occupied on either side by two compound horizontal stationary Marshall engines of 20 h.p. nominal each, driving a line of shafting from which are run seven dynamos. The first is an Edison-Hopkinson shunt machine, whose current at 130 volts, of 144 amperes, is led off to charge a set of 54 large E.P.S. accumulators—31 L type. These have a large and handsomely mounted switch-board, made by the Electrical Power Storage Company, for regulating the discharge, and an automatic charging cut-out of Elwell and Parker is used to prevent back current. The next dynamo is a Phœnix machine, by Paterson and Cooper, compound-wound, giving 250 amperes at 65 volts, and used for running both incandescent and arc lights. The arc lamps for this circuit are of a new and very satisfactory type, recently brought out by Messrs. Paterson and Cooper, in which the feed is regulated by a friction-wheel. These arc lamps are made to run in parallel on the incandescent circuit. Another Phœnix dynamo supplies current for 400 incandescent lamps on a 100 volt circuit. Four other dynamo Phœnix arc machines feed three circuits of 13 or 14 arc lamps in series, one dynamo being a spare one. These give 630 volts and a current of 8·5 amperes, and supply 40 Pilsen arc lamps, which are made under royalty by Paterson and Cooper. Switch-boards are arranged for each of these circuits, lighting (1) the outside and the windows, (2) the counting-house and domes, (3) the costume-rooms and boys' department. Each of these circuits has its own ammeter and resistance, and can be switched on to the spare dynamo if required. Another main switch-board is used for the incandescent circuit, which can be either run from the Phœnix dynamo or from the accumulators, which are sufficient to supply 100 16-c.p. lamps. A Cardew voltmeter is used to regulate the pressure.

A separate compartment is arranged for the accumulators, with a partition between it and the engine-room. The boilers for this plant consist of two Marshall's locomotive boilers, 20 h.p. nominal, with water-heater fixed on a separate basement. A further boiler, of 25 h.p. capacity, is to be added at once. The behaviour of the Marshall engines and boilers has been remarkably satisfactory, both in running and in economy. Little or no trouble has been experienced, and the expenditure of coal is put down at not more than 2lb. of coal per h.p. hour.

One very interesting point is the method by which the mourning-shop in Regent-street is connected to the main building, which is on the other side of Oxford-street. Leave was obtained from the two parishes to take up the roadway of Oxford-street, and a 4in. iron pipe was laid, in which two cables of 19-10 insulated copper wire were drawn through. This supplies 30 arc lamps and 25 incandescent lamps in parallel. An electric bell wire is also drawn in the tube, and a tarred rope, by means of which, wrapped at one end with flannel, any damp can be cleaned out periodically, or further cables could be drawn through if required. The boot-shop and Oriental bric-a-brac shop at 212, Oxford-street is supplied from the main building with six arcs and 60 incandescent lamps. The pressure at the terminals for the incandescent circuit is 108 volts, giving about 101 or 100 at the lamps. Very little trouble is experienced with the running of the incandescent lamps, about 25 per cent. or even less of the number being replaced, indicating a four years' life per lamp, and they have never had but one fuse go—that was for a single lamp short-circuited by a screw.

The switches, made by Paterson and Cooper, are in boxes controlling each room or circuit; but greater satisfaction and convenience is felt with switches on every lamp, and this is being done with the later lamps, and many of the old ones have self switches in the holders. The holders throughout are screw sockets for Edison-Swan 16-c.p. lamps. The fittings were all specially made by Messrs. Verity and Sons, of King-street, the old gas fittings having all been taken down. They are for the most part three, four, or five-light combined gas and electric pendants; one light remains alight while the current is on, the others can be turned on or off with switches. Very great comfort and gain is obtained with the electric light, the comfort to the workers being very noticeable. The saving of goods is also considerable, gas both rotting and fading many of the fabrics. By the arc lights, goods can be matched at night as well as in the daytime, and the white-washing of the premises has not been needed this season. Messrs. Robinson and Co. are much pleased with the arc lamps working in parallel, supplied by Paterson and Cooper, finding it a great convenience to be able to turn off any number or to light up three or four only at pleasure, whereas with series lighting four or five at most could be turned off without danger to the rest. The whole installation is very complete and well arranged, and its success should prove an encouragement for other establishments of the same nature to adopt the light.

ELECTRIC FIRE ENGINES.

To the Editor of The Electrical Engineer.

Sir,—I read with some interest the paragraph in the current issue of your paper on the use of electric fire-engines. I have often wondered that firms making dynamos and motors have not given more attention to this subject.

It may interest your readers—though the information may be somewhat of a disappointment to the inventor to whom you refer—to know that the plan was tried on a practical scale in St. Petersburg, in August, 1881, by M. Tchikoleff.

In the experiments I refer to, a lead was taken from the Arcadia Music Hall, where the electric light was installed, to the banks of the Neva, and there the electric current was employed to feed an electro-motor actuating two pumps. The first pump was employed to raise water from the river to a tank, whilst the second, a force pump, was employed to force the water through a hose and jet in the usual manner.

The experiments clearly showed the advantages of this system. The motor and pumps might have been enclosed in a box of about 3ft. side; and appeared to be about as powerful as one of the ordinary steam fire-engines. The electrical energy, so far as I know, was not measured, so that I am unfortunately unable to give any figures. The advantage in transport through the street of a small motor and pump, instead of a steam fire-engine, and the simplicity with which the connections could be made, and the electro-meter set to work, compared with the trouble of getting up steam in an ordinary steam fire-engine, was clearly shown. The advantage of having terminals at each fire-plug in connection with conductors passing to a central station was dwelt upon by M. Tchikoleff, who also pointed out that until such a centralised system were adopted the plan could easily be carried out on a smaller scale wherever a continuous-current electric light installation was set up.

M. Tchikoleff calculated that the cost of delivering 12,000 litres of water per hour in the manner mentioned was from 4d. to 6d. per hour. Such an estimate is, however, very incomplete.

The credit of the application of electricity for this purpose would appear to be due to M. Tchikoleff.—Yours, &c.,

J. G. Lorrain.

Norfolk House, Strand, W.C., July 11.

THE
ELECTRICAL ENGINEER.

Published every Friday.
Price Threepence; Post Free, Threepence Halfpenny.
Editorial and Publishing Offices:
139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months.	6 months.	12 months.
United Kingdom.....	3s. 3d.	6s. 6d.	13s. 0d.
Within the Postal Union	4s. 4d.	8s. 8d.	17s. 4d.
Other Places.....	4s. 10d.	9s. 8d.	19s 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

A letter awaits No. 28.

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, ESQ., *President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of* W. H. WOLLASTON, M.D., F.R.S., *and on April 20th we gave that of* SIR HUMPHRY DAVY, F.R.S., *whose fame as an electrician is still more prominent than that of* WOLLASTON. *Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of* PROF. D. E. HUGHES, F.R.S.

ARCHITECTS.

Electric lighting in the immediate future will be, and must necessarily be, largely influenced by the attitude of architects. If in their judgment the introduction of such lighting aids them in producing a more attractive and a better lighted interior, assists in producing a *mise en scene* more in accordance with the tenets of the particular fashion that at the moment is the rage, then architects will undoubtedly for their own purposes introduce the light wherever and whenever possible. The word of the architect is law in many cases; his suggestions are supposed by his clients to be infallible, and as such to be followed out at whatever expense. If our contention is correct, one way of increasing business is by educating the architect. The public appeals to the architect, and the latter, if he knows, advises according to his knowledge; but, on the other hand, accepting that he so advises when he is ignorant of the whole subject, the advice must necessarily be somewhat on the lines, Don't at present interfere with the old-established systems of lighting; this new-fangled way is only in its infancy, and you will do better by waiting, as it will be more perfect by-and-by. The result is that a large mansion is built, but not at once provided with the electric light, and it may be this generation loses the business; for it is far more difficult to oust gas when the pipes are laid, and the chandeliers designed, made and fixed, than it is to substitute electricity for gas in the initial stages of the architect's work. The waiting for perfection argument is one of the most illogical and idiotic ever invented by the man utterly void of self-reliance. If we waited for the perfection of anything we should have to wait till the millenium, and that would be a little too long for the great majority. Steam-engines were used before they were perfected; indeed, if we reason from the Patent Office records, they are yet far from perfect.

There are a number of electric light engineers who, to ingratiate themselves with enquirers, do not fail to reiterate the statement that the gas fittings can be easily utilised for electric light purposes. The sooner a decided stand is made against this method of doing business the better. Gas fittings are not suited for electric light purposes, and if so used, are, at the best, only bad makeshifts. What we want to impress upon the architect is the suitability of the electric light for his purposes, and the advisability of providing for such a light from the commencement of his designs. When he understands its suitability and undertakes its provision, we have further to educate him in the necessary precautions and requirements of the system. Wires are not to be built into the walls haphazard, but should be so placed as to be harmless and easily accessible.

From all points of view, then, the influence of the architect is of the utmost importance to the progress

Digitized by Google

of the industry. A certain percentage will always investigate and support a new departure if the investigation has been satisfactory; but it can hardly be expected that the ordinary architect will of his own free will take upon his shoulders the obtaining of correct information about a new science and its applications. He has now to be something of a geologist, a mechanician, a mathematician, and an artist, besides being familiar with the work of bricklayers, stonemasons, plasterers, carpenters, slaters, and all the other trades which are called in to take part in the building of a house. As a sanitary engineer he is supposed to have reached perfection, for whatever goes wrong in the manner of sanitation the fault is laid at the door of the architect. At the present moment, perhaps, the connection of the architect and the electrical engineer is almost entirely confined to electric lighting, but it is quite certain that this in the immediate future will be but one link in the connecting chain. One of our most eminent doctors not so very long ago gave reins to his imagination and described a perfect city—Utopia. We might attempt, but we should lamentably fail, to describe the part electricity is destined to play in our household economy. It should give us light—it should give us power. Why should it not lock and unlock all our doors, and secure our windows from burglarious attacks? Of course we cannot prevent the breaking of a pane of glass or of the panel of a door, but there is no difficulty in so arranging electric apparatus that no door or window can possibly be opened in the ordinary way. The expense to utilise the services of electricity will be comparatively small when the architect provides for its use from the first. There is no reason for door-knobs or keyholes; an electromagnet can form a key as efficient as any ever found out by Chubb. Indeed it would not be very difficult to provide an instantaneous punishment for anyone attempting to tamper with the fastenings of doors and windows, or at any rate to guarantee immediate detection. The vista of possible business when the applications of electricity becomes so general is entrancing, and its realisation depends upon the way we manage to educate the architect. Let him be recognised as a power, and be treated accordingly.

CORRESPONDENCE.

UNITED TELEPHONE CO. *v.* EQUITABLE TELEPHONE ASSOCIATION, LIMITED.

To the Editor of the Electrical Engineer.

Sir,—Having been under the impression that it was a gross impropriety to express an opinion on the merits of a case *sub judice* we have hitherto as far as possible studiously refrained from dealing in a public manner with the persistent efforts made on behalf of the United Telephone Co. to damage our interests in the eyes of the public as well as of their own shareholders and to try and intimidate those to whom we have supplied instruments. But as the Chairman of the United Company has not hesitated to make public, through his speech on 3rd inst., as reported in your issue of 6th inst., a legal opinion on the probable result (from his company's point of view) of the action now pending between the United Telegraph Company and ourselves, we think we need no longer hesitate to say that we have as much confidence in the result being in our favour as the United Company's solicitor professes to have on his side, and that we have the opinion of counsel, if not quite so eminent, at any rate as painstaking as the Attorney-General, that our instruments are not infringements on the United Company's patents. As regards our association fighting the case out, the solicitor of the United Company may certainly be complimented on his sagacity in this respect, and if our association is but a small company compared with the huge monopoly the United Company strives for, we can assure the latter that there are willing purses prepared to find the money to attempt, at least, to break down such a monopoly.—Yours, &c.,

A. E. C. Swinton, Director,
The Equitable Telephone Association, Limited.
July 7, 1888.

ELECTRICAL QUACKS AND GALVANIC BELTS.

To the Editor of The Electrical Engineer.

Sir,—With the object of exterminating electrical quacks and galvanic belt frauds, a subscription list has been started in order to publish in pamphlet form the excellent report and a portion of the correspondence on the above subject which has recently appeared in the columns of the *Electrical Review*, London. A committee is being formed in order to effectually carry out this benevolent scheme. I shall be glad to receive assistance in any way from any of your readers.—Yours, &c.,

J. Jerritt, A.S.T.E. and E., sec. *pro tem.*
Mutley, Plymouth, July 9, 1888.

[We are pleased to insert the above letter, and recommend the co-operation of our readers with the objects therein expressed.—Ed. *E. E.*]

DETECTOR FOR HOT BEARINGS.

To the Editor of The Electrical Engineer.

Sir,—In your issue of the 29th ult. Mr. Broadbent says that hot bearings should not occur. Very true; yet he will not deny that often, in spite of care, ships are "brought up" through this cause, and delay, expense, and trouble are the result. Again, the tendency to increase the speed of engines makes more than ever the "feeling" of crank-pins when running a matter of guesswork.

Still, I agree with him that to leave the replacing of fusible plugs, or anything to be done to a heating detector, after giving an alarm, is fatal to its reliability, and also that the alarm should be given at any *required* temperature when the heating is *beginning*.

I have, in conjunction with others, invented an instrument which has been manufactured by Messrs. Elliott Brothers, of St. Martin's-lane, London, who will be glad to show the same to anyone interested in the subject. This simple arrangement may be fitted in the top brass of a crank-pin, and connected by two wires to a small battery and bell fixed to the bottom of connecting rod. By a simple adjustment any temperature desired may be denoted, and when not only the whole but any *part* of the bearing is *beginning* to heat the bell will ring. It can be fitted to any bearing. The only attention required is the recharging of the battery, say, every six months. There is no complication, and it can only be put out of order deliberately.—Yours, &c., W. T. W. Thackeray.
9th July, 1888.

The Americans Use Them.—As soon as the Americans get hold of anything that will work, they apply it. All the improvements in dynamos and in motors have practically been rejected on this side of the Atlantic. We seem to make the improvements for the Americans to make use of.—*W. M. Mordey.*

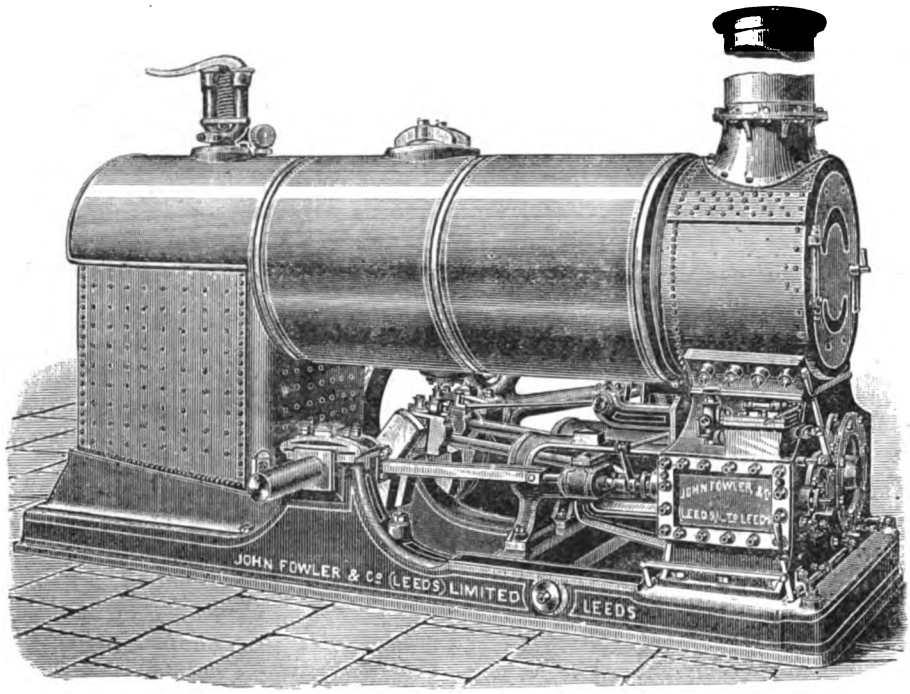
ROYAL AGRICULTURAL SOCIETY'S SHOW, NOTTINGHAM.

The Royal Agricultural Society's Show, held this year, for the first time in its history, at Nottingham, contains few exhibits of any great interest to electricians. In one department, however, as year succeeds year, there are exhibits specially fitted for the examination of the electrical engineer. We refer to the engines shown by the large engine firms. At the present time, four or five different types of engines are used for installation work. A small temporary installation is often run by a portable engine. Other installations derive their power from the semi-portable — undertype engines — while the larger installations have fixed engines. Then we have fast-speed direct drivers, for work requiring another class of engines; and where accumulators are used, gas-engines are also largely used. Engine makers have almost unanimously come to the conclusion that the so-called semi-portable undertype of engine is the one best suited to the present need of the electrical engineer, and they exhibit these engines as "admirably suited for electric lighting purposes." Upon examination of the exhibits excellent engines of this class will be found at the stand of Messrs. J. Fowler and Co., Messrs. Ruston and Proctor, Messrs. Ransomes, Sims, and Jefferies, Messrs. Robey and Co., Messrs. Marshall and Sons, and others, and it may be worth while just to pass these engines in brief review before our readers.

A technical description is not called for, inasmuch as the engines built by the firms we mention are known to be first-class productions; and because the makers have a reputation to consider, it may almost be taken for granted that their productions are from well-considered designs and from the best materials. It is absolutely impossible for us to say this or that engine is better than those of other makers. There are a good many considerations to be taken into account in determining "the best," and these considerations are such that no trial or series of trials being carried out or attempted will enable any man to come to an absolute decision upon this question. Time is a most important factor in almost all mundane affairs, and time tells a good deal more about the cost of maintenance than any other method ever devised. The very fact, then, that the productions of certain firms are preferred before others is almost conclusive testimony that experience shows these productions cost less in maintenance than those of competing firms. A stringent trial of engines, like that of last year by the society at Newcastle, brings out one that under the conditions then holding is shown to be somewhat better than the rest. Messrs. Davey, Paxman, and Co. then secured the much coveted prize, and the records of the society show other firms similarly successful in the past. This means that the engines of several makers are almost or quite equally good. And business must be obtained, not because of any great predominance, but by tact and attention to special details required for special purposes. We could wish, however, that engineers would agree as to some better method of indicating the power of an engine than by stating it to be so many horse-power nominal. Really, students are handicapped as far as possible in every direction—it would seem stupidly so, and for the sole purpose of keeping information from them. Knowledge is power, says the old adage; get knowledge, say the greybeards, but at the same time those who have the knowledge take care it is not easily obtained by others. The student soon finds out that horse-power nominal means anything or nothing, and that size of cylinder, length of stroke, or indicated horse-power are really what he should know. Most of the best makers reckon the normal work—that is, the work best suited for the engine is from 2½ to 3 times the nominal horse-power—in other words a 20 h.p. engine is supposed to be worked so as to give 50 to 60 i.h.p.



Messrs. Fowler and Co.'s 12-h.p. Semi-Portable Engine.

The value of the undertype engine in saving cost of foundations, minimising vibration, and in various other ways need not be dwelt upon here.

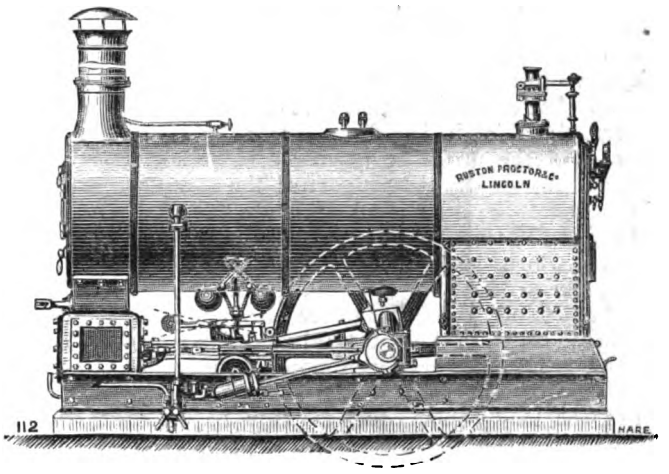
Messrs. J. Fowler and Co., of Leeds, show a 12-h.p. semi-portable engine, which is also specially constructed for electric lighting. This engine is similar to the one used last year at the Saltaire exhibition, which is now in use by Messrs. Laing, Wharton and Down in their installation at St. Pancras. The engine, which is herewith illustrated, is fitted with Hartnell's patent automatic expansion gear on both cylinders. Messrs. Fowler maintain this is the proper thing to do when the power given off by each cylinder is to be equal under varying loads, as is the case in electric lighting work. We are informed that by the method adopted of governing this engine it is incapable of exceeding by more than 1 or 2 per cent. its mean speed when the load is suddenly removed, and will not fall below the mean speed by a greater amount when the whole load is suddenly thrown on. In practice, a small fraction of 1 per cent. variation of speed begins to alter the degree of expansion, a result not obtained with ordinary governors. It will, however, be quite within the knowledge of our readers that every firm of repute that undertakes the construction of electric light engines pays special attention to the governing of the engines.

Messrs. Fowler and Co. also display a case of samples of "Tatham's" patent lead-covered cables and wires for all kinds of electrical work, telegraph, telephone, and electric

Digitized by Google

light, of which they are the sole manufacturers for Europe and the colonies. These cables are said to be specially suited for underground work of every description, being used in mines, the beds of rivers, docks, and for ordinary telegraph and telephone work. For lighting factories, chemical works and ships, these lead-covered cables have much to recommend them. The lead is put on continuously and not in short lengths, thereby greatly lessening the number of joints required in long lengths and large installations. The insulation of these cables is given as exceedingly high and of great mechanical strength. It is unaffected by heat. The telephone cables (1 to 104 wires in the same cable) are made on a patent principle, by means of which the troubles of induction and bad language are said to be removed, but in this place, while describing the exhibits at a Royal Agricultural Show, we must restrict our remarks, and reserve for future consideration the peculiarities and adaptabilities of this new insulating compound and method of protecting the conductors.

Messrs. Ruston and Proctor show a 16-h.p. nominal semi-fixed undertype engine, specially designed for the driving of dynamos. The high-pressure cylinder is 8in. in diameter, and the low-pressure 12¾in., both having a 16in. stroke. The most economical load of this engine is given at 40 h.p., the maximum as 48 h.p. Taking that seven 16 candle incandescent lamps are obtained from 1 i.h.p., this engine is powerful enough to drive a dynamo to give about 300 lamps, and in most cases this would represent a wiring of at least 500 lamps. These roughly approximate calculations can be applied in the case of all other engines



Messrs. Ruston, Proctor and Co.'s 16-h.p. Semi-Fixed Under-Type Engine.

mentioned. Each part of the engine has received special attention, and the makers are ready with good reasons why their particular method or material is to be preferred. Automatic expansion gear is fitted to the high-pressure cylinder, and great care has been taken to make the governing satisfactory. The boiler is of the multitubular type, and designed for a working pressure of 120lb.

NOTES ON DYNAMO CONSTRUCTION.

BY SYDNEY F. WALKER.

Thanks to the labours of the Hopkinsons, Silvanus Thompson, Kapp, and others, the construction of dynamo electric machines has now approached a definite stage; but much yet remains to be done. There is no recognised form of dynamo, although the Gramme, the disc, and the drum armatures are all free from patent rights. At present anyone wishing to take up the manufacture of dynamos is bewildered by the numerous forms of the article—all of them different, and each claiming to be *par excellence*, not only the best, but far and away superior to every other.

The following notes have been written with a view of clearing the ground as far as possible, and pointing out the practical advantages and disadvantages of each type. To begin, then, there is really very little to choose between the different patterns, provided that all are equally well made, and conform to certain conditions that will be detailed. The differences between the various types of machine, except where explained, are mere differences of detail, brought about in many cases by the wish of the designer to have something different to the Gramme so long as the latter held the field, and in other cases by the idiosyncracies of individual inventors. But the greatest diversities of ideas prevail in their construction. One man's aim has been to reduce the amount of copper used in his machine, and he will proudly tell you that he gets so many watts per lb. of copper. Another holds the opinion that the great desideratum for dynamos is, that they should run at a low speed; a third will tell you that he only uses wrought iron in the construction of his machines. One set of makers construct the armatures of their dynamos in the form of a long cylinder; another set, in the form of short cylinder; a third in the form of a drum; and a fourth in the form of a disc. One set of makers construct their field-magnets in the form of a single horse-shoe; another set, in form of a double horse-shoe; and a third have several horse-shoes. In the case of some makers, the machines of two, or even all, of the above types are made. One set of makers run their armatures at right angles to the line of the field-magnets, and others parallel with them, and so the changes go on.

It must be remembered that there are two parts to the problem in designing a dynamo, the electrical and the mechanical.

The useful output of a dynamo, as is well known, is the product of the largest current the dynamo is capable of furnishing × by the E.M.F. at its terminals when furnishing that current, and running at the highest safe speed if variable, or at the normal speed if the latter is constant. The E.M.F. at the terminals, as is also well known, is the total E.M.F. produced by the armature, less a charge measured by the product of the resistances of the armature and series wire on field-magnets, where there is one, × by the current. The total E.M.F. of the armature is proportional to the product of the speed, the number of turns of wire on it, and the number of lines of force passing into it across the space occupied by the copper wire. Using Mr. Kapp's formula – $Ea = \frac{NTnZ}{1{,}000{,}000}$ where Ea = total E.M.F. generated by the armature; in volts, N T = the number of turns of wire on the armature, reckoned all round its periphery; n = the number of revolutions per minute; Z = the number of Kapp's lines passing into the armature. Mr. Kapp has been taken very seriously to task for his notation, but as manufacturers want to know the volts they may expect, and care very little for absolute units, most of them incline very strongly to Mr. Kapp's views on the subject. It is evident from the formula that a given E.M.F. may be generated by any combination of the above quantities that is convenient. Thus, you may have a very small dynamo with a very light armature running at a very high speed. The best illustration of this is the dynamo attached to Parson's steam turbine, which runs at some 9,000 to 12,000 revolutions per minute; but it appears to the writer that you cannot easily get the full benefit of these very high speeds. Although the dynamo and engine of Messrs. Parsons' works remarkably well and form a striking instance of the possibility of using very high speeds, it is doubtful if they are able to obtain their full advantage in the reduced size of the machine, and it is also very doubtful if the machines are as efficient. The writer understands that the core of the armature heats considerably, as naturally might be expected under the very rapid alternations of magnetism. This could, of course, be remedied by having no iron in the armature, though that would lead to a loss from the increase of the resistance of the magnetic circuit. It could be more efficiently disposed of by making the core of the armature stationary, and allowing the wire only to revolve, or by arranging a special design. When using these very high speeds, too, it is necessary to provide for the greatly increased friction; this difficulty appears to have been quite overcome in Messrs. Parsons' apparatus, and the whole arrangement shows great care and skill in designing and workmanship.

You may also have a very powerful magnetic field, the factor Z being very large, while the others remain small. This, however, necessitates increased size in the dynamo. In order that Z may be large, the quotient of

Digitized by Google

the exciting power, divided by the magnetic resistance, or $\frac{P}{R}$, must also be large. This means that P must be very large or R very small. You can only accomplish either of these ends by making your machine big and heavy. It has been established that iron, even of the very best quality, will only transmit a certain number of lines of force without beginning to increase its magnetic resistance; and, moreover, it is necessary that its cross section shall be large in order that its magnetic resistance shall be low. Secondly, in every dynamo the winding-space for wire is limited by the construction of the machine, so that if greater magnetising power is required it can only be obtained by increasing the dimensions of the winding-space, and usually with it those of the entire machine. Even in those few cases where it is possible to wind an increased number of turns on without alteration, it must be remembered that as each layer is wound further and further from the core its inductive effect upon the iron becomes less and less. The above remarks as to size apply equally to the armature and to the field-magnets, as they both have to accommodate the same number of lines of force. There is also a practical limit to the number of lines of force per square inch that you can advantageously make use of in the core of the armature, owing to the heating due to the alternations of the direction of magnetisation; and in practice it is found that dynamos work better the lower the strength of magnetisation. And, thirdly, the required E.M.F. may be obtained by means of a weak field and moderate speed, if the number of turns of wire on the armature are large; but this only within certain limits, and there are many practical objections to it. In the first place, in order to increase the number of turns, you must either decrease the size of the wire on the armature, thereby decreasing the output of the machine, as the armature will now only furnish a smaller current than before without unduly heating; or you must increase the number of layers of wires, in which case, as you throw the iron core of the armature further back from the pole-pieces, and at the same time decrease the volume of iron in the core to make room for the additional layers of copper wire, you add very considerably to the resistance of the magnetic circuit. Further, whether you decrease the size of the wire on the armature or increase its length, you increase the armature-resistance, and with it the charge upon the initial E.M.F. generated. The apparent added resistance of the armature, due to self-induction of its coils, and with it the working resistance, is also increased, as is the sparking at the brushes, all being sources of loss. The best type of machine would therefore evidently be that in which Z was large and the other factors comparatively small; but if we go too far in this direction we may buy our apparent efficiency too dearly.

Here it should be noted that large machines and small ones are not exactly on all fours in this matter. Where we are consuming, say, 100 h.p. or 1,000 h.p. a saving of 5 per cent., or even 1 per cent., may be worth having if not purchased too dearly—that is to say, if the interest on the increased cost of the machine to enable us to make this saving does not exceed the annual cost of the power saved. In small machines, using, say, 5 h.p. or 10 h.p., a saving of even 5 per cent. after a certain efficiency is attained would in most cases be too dearly bought, owing to the increase of the size and delicacy of the machine necessary to enable the extra saving to be attained. The increased cost in large machines also would be principally represented by metal, upon which not much labour has been expended, while in small machines more of it would be for labour. The manufacturer will, therefore, probably design his machines for large work, large; and in those for smaller work he will strike a mean, getting his speed as high as he can, his magnetic field as strong as possible, and making up with turns of wire; but the test in each case will be the cost of production. The price he can obtain for his finished machine is beyond his control, so that the amount of profit he is able to make will depend upon the design of his machine from a structural point of view. A saving of copper on the armature will be no gain if the same money value or more is lost by the increased cost of machining the iron work; and again, though iron costs less than copper, there will be no saving if the value of the extra weight of iron exceeds that of the copper displaced. The limit, apparently, to iron displacing copper is reached when the value of the extra weight of iron, plus the value of the extra machining and handling, plus the value of driving power saved, if any, equals that of the copper displaced, plus the saving in winding, if any. It will be evident, also, that the value of the increased efficiency will vary very considerably under different conditions, such as the price of coal, the cost of attendance, &c.

One of the first points a manufacturer has to decide is the form of his machine. Shall the armature be a long cylinder, a short one, a drum, or a disc? Shall the field-magnets be single, horse-shoe, or double, or shall the dynamo be multipolar? Shall the axis of rotation of the armature be parallel with the field-magnets, or at right angles? These points may seem trivial in themselves; but they will often make a considerable difference in the cost. Upon the form of the armature and field-magnets the magnetic resistance depends, and therefore, in part, the efficiency of the machine. The magnetic resistance depends directly upon the length of the magnetic circuit, and the materials of which it is composed, and inversely on its cross section. Thus air, as is well known, has an enormously greater resistance that iron, consequently everything is done to reduce the length of the air space in the direction of the lines of force, and to increase its cross section. This points to a long bobbin and to very few layers of wire between the core and the pole-pieces, and those as thin as possible. In many modern dynamos, only one layer is used for incandescent machines. In the Pacinotti form, projections on the core are brought right up the pole-pieces, allowing, of course, the usual clearance, but here an unforseen source of loss has crept in, owing to the heating of the pole-pieces, due to the teeth of the armature causing too rapid variations of the resistance in that part of the magnetic circuit. To remedy this, it has been necessary to reduce the diameter of the armature, leaving a larger air space, and thereby neutralising at least part of the advantage gained. It remains to be seen if an armature wholly of iron has this defect. The armature recently designed by Mr. Charles Lever, in which the teeth are run in grooves in the pole-pieces, carries the Pacinotti principle a step further, but would apparently be subject to the same faults as the latter, and in addition, to the structural objection that the whole machine has to be very much more carefully fitted, and is therefore more expensive.

But the long bobbin cannot easily be arranged with machines in which the armature runs parallel with the line of the field-magnets, without either making some special arrangement for the commutator, such as placing it outside the machine, or by lengthening the whole machine, in which case you have increased your magnetic resistance again. This would appear to argue in favour of those machines in which the axis of rotation of the armature is at right angles to the line of the field-magnets, and for this reason doubtless many manufacturers have adopted that plan. Before deciding definitely to adopt the long bobbin, and the armature at right angles to the field-magnets, a maker would do well to go into the question of the mechanical construction of the machine, which plan will work out best in the fitting shop, because it may easily happen that in order to obtain the advantages of a certain form of bobbin he will have to pay more for fitting, and he may also discover that all or nearly all that he can attain by means of that particular bobbin can be obtained equally as well by means of another form by the simple process of neutralising a loss in one direction by a gain in another. The problem to be solved is, to construct a dynamo as cheaply as those in the market, and as efficient—that is to say, to get as much work as possible out of a machine, costing a certain amount for the materials and labour, and to attain the work with as little loss between the driving pulley and the terminals of the machine as possible. If we produce a machine that is cheap, but that obliges the purchaser to consume more coal than another machine, our machine may not be really cheap after all. But, on the other hand, we must be careful not to so complicate our machine in obtaining so-called increased efficiency that we make the extra cost of attendance due to this complication greater than the amount saved by the increased efficiency, nor by increasing

Digitized by Google

the return at the terminals of the power given to the pulley to increase the cost of repairs to the machine.

Five per cent., or even 10 per cent., extra efficiency, would be dearly bought if the repairing account were largely increased in consequence. A machine giving 80 per cent., or even less, that would run year after year with little or no trouble, would be more efficient in the true sense of the term than one giving 95 per cent. or 98 per cent., that constantly needed repairing, or in which the repairs were expensive when they did come. It is an old rule in practical work that the last 5 per cent. efficiency takes a great deal of keeping up, whether it is in an engine, a pump, a dynamo, or any other apparatus. It usually depends upon some special fitting requiring special men—and often very expensive ones—and special tools to repair it from time to time.

The best machine is always the one that can be easiest repaired, other things being the same. We must also be careful not to err on the opposite side: not to construct our machine mechanically weak, or in any way sacrifice the durability of any of its parts for the purpose of making a cheap machine. The real test is the working cost of the whole apparatus.

Let us consider what are the losses or charges to which we have to submit. First, we have friction, due to the spindle of the bobbin revolving in its bearings. This will vary directly with the weight and with the speed Here, then, is one argument against both long bobbins and very high speeds, since the former must necessarily be heavier, or else some of the advantage given by length is lost by the decreased section of the core. Next, we have the charge for magnetising the field-magnets, for providing the lines of force. Unless we pay this toll we can have no current furnished. The charge under this head varies inversely as the magnetic resistance. The more we can reduce this the less power we require to do certain work, or to produce a given number of lines of force. This resistance, as Mr. Kapp has shown, consists of three parts: the resistance of the field-magnets and their yoke, the resistance of the core of the armature, and that of the air space and copper wire. Of these, the resistance of the air space is enormously greater than that of any other part for a given section; and further, cast iron, of which standards and pole-pieces are usually made, has a higher resistance than wrought iron. The resistance of each of these varies directly with their length in the direction of the lines of force, and inversely with their cross section. This would point again to a long bobbin, and to short and thick magnets, provided the necessary exciting power can be placed on them.

(To be continued.)

DETECTOR FOR HOT BEARINGS.

With reference to our note upon the question of detectors for hot bearings, we have received a letter from Mr. W. T. W. Thackeray, which we print in our correspondence columns, calling attention to patent No. 3827 granted to him in last year, in conjunction with the widow of H. R. Landon, electrician, and the widow of John Richardson, instrument maker, for apparatus which will enable the beginning of any slight increase of heat in the bearings to be noticed before any real damage in done.

The apparatus consists of a reservoir of suitable shape in connection with a "Bourdon" tube, the reservoir and tube being filled with gas or liquid having expansive properties. The free end of the "Bourdon" tube may be connected to a lever for multiplying the motion caused by expansion or contraction of the liquid or gas, and the lever can be made to pass over one or more electrical contacts in connection with an electric bell. The lever can be arranged, if preferred, to relieve a spring, setting in motion a clockwork alarum or other mechanical contrivance for the same purpose.

By these means, for instance, any particular degree of expansion desired to be indicated, such as would be caused by the heating of journals or bearings of steam or other engines, can be automatically signalled to the engineer. It can also be made to indicate the presence of fire in buildings.

In the accompanying drawings, Fig. 1 represents a front elevation of the apparatus. Fig. 2 is a front elevation of a connecting rod head of a marine engine, with the apparatus fitted to the upper brass, and in connection with an electric battery and bell attached to the rod.

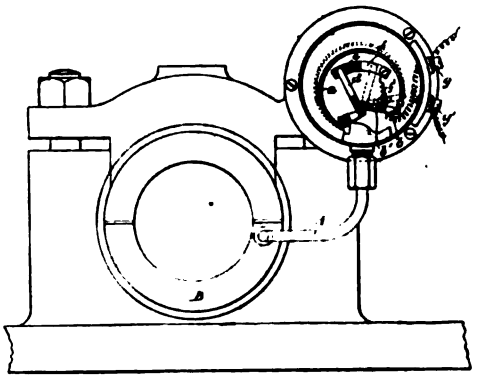


FIG. 1.

The reservoir, A, is filled with gas or liquid having considerable expansive properties under the action of heat, and is connected to the "Bourdon" tube, *a*, the free end of which is attached to the slotted and adjustable lever, *b*, the length of which is regulated by set-screw, b^1. The outer end of lever *b* is attached at any desired point to pivoted contact-maker, *d*, the free end of which is shown in full lines as resting on insulating piece, *e*, which may be of vulcanite or other suitable material. Any heating of bearing, B, would impart heat to reservoir, A, the result being the movement of tube, *a*, with connected levers *b*, *d*, the latter being drawn over on to contact-piece, *f*, as indicated by dotted lines, and the circuit being completed through the terminals *g*, g^1, an electric bell or other alarm will be sounded. It will be obvious with apparatus constructed as described that contact piece, *f*, must not be in electrical communication with both terminals except when lever *d* rests thereon, and to this end the said contact piece is insulated from the metal casing by being screwed into a recess in the face of the insulating block, *e*, a wire, f^1, serving to complete the communication with the terminal *g*, the other terminal, g^1, being, of course, in connection with the casing, the "Bourdon" tube and levers *b*, *d*.

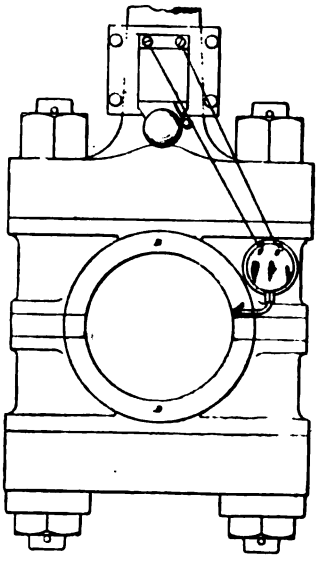

FIG. 2.

It will be also obvious that lever *d* may be used to liberate a spring, setting in motion a clockwork alarum, or other mechanical contrivance for the purpose, if desired.

The apparatus is especially valuable for use on marine engines, as when the connecting rod is in motion it is always difficult to ascertain if the brasses are heating, and is likely also to have extended use in long running machinery for central station lighting.

The use of a "Bourdon" tube in this connection is not absolutely new, but the device of electrical indication of change of temperature, even when slight, automatically in the manner described is the claim of this patent.

Digitized by Google

The invention was the outcome of long experiments on shipboard, and it has been applied to one steamer for some time. It practically answers all requirements, and when once fitted does not interfere with the removal of brasses (except to detach wires), and is strong enough to stand a reasonable amount of rough usage, and the parts being made non-corrosive and enclosed in brass box is not affected by water, steam, &c.

As a fire-alarm also it may be fitted to holds of ships, &c., and as the reservoir tube can be made of some length it is useful for purposes that other apparatus is not suitable for.

THE CONSTRUCTION OF DYNAMO-ELECTRIC MACHINES.

BY CECIL P. POOLE.

While there are several valuable works which treat of this subject in an able manner, there seems to be no definite method known whereby proper relative proportions and economical individual proportions may be arbitrarily determined for dynamos or motors. Though it is not practicable to give formulæ which will be absolutely correct in all cases, it seems that some means should be known for obtaining approximately accurate results in the designing of dynamos, and reducing to a minimum the necessary corrections to be made after the machine is tested. It has been the good fortune of the writer to have excellent facilities for experimenting in the matter of dynamo proportions and capacity, and the results of these experiments are herewith presented for what they may be worth. The formulæ here given were obtained from tests with Gramme armatures only, but they may easily be modified to meet the cases of other types of armature.

Proportions.—It is desirable to give the armature core the largest possible cross-section with the smallest possible length, per turn, of conductor. Yet there are cases in which it is preferable to slightly increase the resistance of the armature wire, in order to bring the iron in the armature closer to that of the pole-pieces—that is to say, it may be preferable to make the armature core long and thin in cross-section, so as to diminish in thickness the layers of wire, even though a long, thin core requires more wire per turn for a given cross-section than a square core. No investigations are on record as to the dividing line between advantage and disadvantage as the result of elongating the core of a Gramme armature. The writer has found it a good rule to make the armature core of incandescent light or other low-potential machines square in cross-section up to 15,000 watts output, and to restrict the length to twice the radius of the core in such machines of greater output.

The diameter of the armature cannot be determined by any simple formula which will be correct in all cases; but the following rule of thumb will give very good results ordinarily:—

Make the diameter of the armature core 4 to 6 times the radial thickness of the core, according to the nature of the winding. That is, for very few layers of wire use the smaller multiplier, increasing its value as the layers of wire increase, restricting the value, however, to 6.

The cross-sectional area of an armature core should be neither larger nor smaller than is necessary to accommodate the lines of force emanating from the field-magnet. If the former disproportion exists there will be a waste of iron in the armature; if the latter, a waste of iron in the field; while in either case the amount of copper on both armature and field will be excessive for the output of the machine. As the iron generally used in armatures is of a much finer quality than the best wrought iron ordinarily used for field-magnets the relative cross-sections should be fixed by the ratio between the quality of the iron in the field and that of the armature core.

Taking into consideration the varying quality of iron in the field and the leakage of some of the lines of force created therein, the following formulæ will be found to give good practical results:

For arc light, or other high potential machines, with malleable cast-iron magnet cores:

$$F_s = \frac{4{\cdot}8\ A_a}{f}; \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

and if the magnet cores are wrought iron,

$$F_s = \frac{3\ A_a}{f}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

For incandescent light, or other low-potential machines with cast-iron magnet cores the formula becomes—

$$F_s = \frac{4\ A_a}{f}; \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

and if the cores are of wrought iron,

$$F_s = \frac{2{\cdot}5\ A_a}{f}. \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

In these formulæ, F_s represents the cross-section of each field-magnet limb in square inches, A_a that of the armature core, and f the number of magnet limbs terminating at each pole-piece.

The pole-pieces should have ample cross-section to allow the passage, without throttling, of the lines of force created by the field-magnets, and to minimise their escape by presenting a path of low resistance, by which they may reach the armature core. It is better to waste iron by having the pole-pieces unnecessarily large than to waste energy by having them too small. At the same time there is no economy in having them embrace so much of the armature circumference that lines of force leap across from pole to pole and do not contribute to the work of inducing electromotive force in the armature wire. From a number of experiments made by the writer it appears that the most advantageous proportion of the armature to be covered by the pole-pieces is ·5 if the armature be wound for high potential, and ·6 for low potential armatures. Hence, for the polar arc in the case of arc light machines,

$$\lambda = \frac{{\cdot}5\ U}{p}; \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

and for incandescent light machines,

$$\lambda = \frac{{\cdot}6\ U}{p}; \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

λ representing the arc of each pole face, U the circumference of the finished armature, and p the number of poles on the machine.

Care should be taken to make the thickness of the pole-pieces in the direction of the lines of force emanating from the magnet as small as possible, so as to get the field-coils near the armature and to reduce the resistance of the magnetic circuit. The writer had facilities for experimenting with only two thicknesses of pole-piece iron, and only one machine, and consequently is unable to give any accurate data in this connection; but the result of the limited experiments made goes to show the advantage of shortening pole-pieces in the direction of the lines of force. In the experiment referred to, an arc light dynamo of similar build to the well-known Excelsior (Hochhausen) machine, with pole-pieces 3in. thick, gave 6,000 watts. With another frame, similar in all respects to the one first used, save that of the pole-pieces, which were made 1½in. thick, the machine gave 6,200 watts, running at exactly the same speed as in the first case. It is, of course, impossible to make any deductions from a single test, and this test is only mentioned to draw attention to a point that, perchance, may not now enjoy a large share of consideration. The length of the pole-pieces parallel with the armature-shaft is naturally dependent upon the length of the armature, and requires no formula.

The form and proportions of field-magnets vary greatly, and it is not practicable to determine them for all machines alike. The conditions under which a machine works and the nature of the work performed will go far toward determining the form and number of field-magnets to be used. Generally speaking, short, round magnets are the most economical, and as dynamo builders are beginning to use this form to a greater extent, perhaps, than any other, we may infer that it is the most advantageous in more respects than one. In something over a hundred tests made by the writer, it was found that the best results are obtained, as regards intensity of field and economy in wire and energy, when the length of a round magnet limb is 1·5 to 2 times its diameter, and the length of an oval core about the same as its width, if tolerably flat.

Consequent pole machines are most commonly used, for no other reason, apparently, than that someone else makes

Digitized by Google

this form, and we follow, like sheep, in their footsteps. For car motors, where light weight is, to a certain extent, a necessity, consequent pole machines are naturally desirable, but under ordinary working conditions, it would seem that dynamos and motors with single magnets are the most economical and to be preferred.

Capacity of Output.—The capacity of an armature may be predetermined by a very simple calculation. It is well known that a wire will generate one absolute unit of E.M.F. for each line of force cut per second, and from this fact, if we assume a given density of lines for the armature core, a rule may be deduced by which the capacity of the armature is quickly and easily determined. Assuming a density of 120,000 C.G.S. lines per square inch in the armature core (Mr. Kapp states that this is a fair average), we find that *each convolution of armature wire will generate ·00004 of a volt for each square inch of core every time it passes a magnet-pole.*

Therefore, the total E.M.F. generated in an armature working at the above-named den·ity will be

$$\text{E.M.F.} = \frac{4\,A_s\,c\,p\,r}{100{,}000};$$

or,
$$\text{E.M.F.} = 4\,A_s\,c\,p\,r\,10^{-5}; \quad . \quad . \quad . \quad (7)$$

where c represents the total number of convolutions of armature wire, r the number of revolutions per minute of the armature, and p the number of poles as before.

As all the convolutions of the armature wire are not in direct series, the result obtained by this formula will have too great a value. In all closed coil Gramme armatures, excepting the Andrews form, the conductor is divided into as many parallel branches as there are poles on the machine, for convenience in commutation. Therefore, the number of convolutions in series will be $\frac{c}{p}$, and the difference of potential at the brushes will be that E.M.F. which is created in $\frac{c}{p}$ convolutions. Hence,

$$\text{E.M.F.} = 4\,A_s\frac{c}{p}\,p\,r\,10^{-5}.$$

But as $\frac{c}{p}\,p$ is equal to c, the factor p is eliminated and the formula becomes

$$\text{E.M.F.} = 4\,A_s\,c\,r\,10^{-5}, \quad . \quad . \quad . \quad . \quad (8)$$

and is applicable to bipolar and multipolar machines alike.

As a density of 120,000 lines per square inch has been assumed for the armature core, the field-magnets will have to be wound so as to supply $A_s p \times 120{,}000$ lines of force in addition to those lines lost by leakage and other causes. A fairly accurate rule for field-winding is as follows:—

Each ampere-winding will impel 2,000 lines of force through a bar of wrought iron one inch long and one inch square in cross-section.

If there were only the resistance of the iron in field and armature to be overcome, the necessary ampere windings would be obtainable by an exceedingly simple equation, but there are two air spaces in every magnetic circuit in a dynamo, and their resistance must be taken into consideration. Allowance must also be made for the lines of force which are lost or wasted. Without going through the deductions by which the formulæ are obtained, it is sufficient to give the following as being tolerably accurate in practice:—The total number of ampere windings on all the magnets of a dynamo, as near as may be calculated before testing the machine, are

$$a\,w = 30\,F_s f p \left(\frac{L}{F_s} + \frac{f u}{2\,A\,p} + \frac{1440\,d}{\lambda\,b}\right), \quad . \quad (9)$$

if the field-magnet cores be wrought iron. For cast-iron cores,

$$a\,w = 20\,F_s f p \left(\frac{1{\cdot}6\,L}{F_s} + \frac{f u}{2\,A_s p} + \frac{1440\,d}{\lambda\,b}\right); \quad . \quad (10)$$

where L = the length of one magnet from pole face to pole face;
u = the mean circumference of the armature core;
d = the distance from the iron of the pole face to that in the armature; and
$\lambda\,b$ = the area of each pole face.*

* In these formulæ Mr. Kapp's estimate of the magnetic resistance of air, 720 times that of wrought iron, is used.

The last four formulæ given, (7), (8), (9), and (10), are based on a density of 120,000 C.G.S. lines per square inch in the armature core, and will, of course, not give good results with any other density; but they may be easily changed so as to be applicable for any other given density.

It is not claimed that they will prove rigorously accurate, and that no corrections will be necessary after testing the dynamo; but the writer has found that a considerable amount of time and trouble may be saved by their use. To make the formulæ applicable for any other given density of lines in the armature core, it is only necessary to alter the coefficient of A_s in (8) and that of F_s in (9) and (10) in the same ratio as the number of lines per square inch in the armature core is altered.—*Electrical Engineer*, New York.

A STUDY OF CERTAIN ERRORS IN THE CONSTANT SHUNT METHOD.*

BY WILLIAM L. PUFFER, S.B.

(Concluded from page 16.)

The largest deflections were always found with the German silver wires, and the least with copper wires with soft-soldered connection. The deflections were seldom twice alike even with the same wires, ranging from 0·0 to 20, being positive at one time and negative at others. The difference between the silver solder and the soft solder was not particularly marked, but seemed to be in favour of the soft solder, both with the copper and German silver leads. These deflections were always smaller and more regular when the shunt was in water than in air. It often happened that the copper soft-soldered leads gave no indications of thermal action, and I never saw any indication of trouble from the double-soldered connection in the middle of the shunt.

This shunt was made to correspond approximately to some of the shunts described in articles on the shunt method of determining currents both in regard to size and length of wire and method of connecting the lead wires.

The thermal action in the standard G. S. shunt was very much greater than in any part or combination of the other shunts, being larger when the copper leads were used by about 7 per cent.; still, even these large thermal E.M.F.'s were quite small when compared to that produced by the calibrating current, and could have been safely neglected if an accuracy of 0·1 per cent. was required. I thought I could now compare this shunt with the standard ohm easily enough; and then with the other shunts by using a current of several amperes, to get so great a difference of potential that the thermal effects would be drowned. I changed the storage battery, letting the current pass through all three shunts, and after a few hours I broke the circuit, and tested the shunts to see whether the current had perceptibly heated them, although a sensitive thermometer showed no change. The copper and large G. S. shunts seemed about as usual, but the standard gave me a deflection of 2,000, which rapidly diminished. This was far too small to be of any effect with this particular shunt, but it was very suggestive. Examination of the shunt showed a slight blackening at the positive end, and a few bubbles of gas; probably due to slight decomposition of water, as the difference of potential had been about 1·8 volts. A reversal of the current caused the blackening to appear at the other end of the shunt, and a slight lessening of the discoloration produced by the previous current.

A current of 22 amperes in all three shunts produced 3·5 volts in the standard, and in breaking 0·00 06 volt at the end of half a minute, which fell to 0·00 000 2 at the end of five minutes. The deflection was in the same direction as when the current was passing, and was reversed by reversing the current. The other shunts gave no such effects even with 60 amperes, so work was chiefly on this shunt. A current of 45 amperes caused an effect which sent the spot off the scale for over a minute.

Curves were plotted, showing the diminution of the thermal effect at equal intervals of time after stopping the main current, which show that while the current is passing, the apparent resistance of the shunt is greatly increased by this action. It appears as if this counter E.M.F. increased with the current, although not quite in the same proportion.

Read at the meeting of the American Academy of Arts and Sciences.

At this point my experiments had to be postponed, so all apparatus was put aside for a number of months, and then set up in exactly the same manner and position, with the exception that I only used the standard German silver shunt, to which I added three new sets of terminals—two of German silver and one of copper, all soft soldered, using acid for a flux.

Experiments were made to find what caused the variable deflection from this shunt after a current had been passing, and to see if there was any noticeable difference in the materials used in the potential leads and solderings. I designated the different sets of leads in the following manner :—

Leads No. 1 were of German silver, soft-soldered.
" " 2 " copper "
" " 3 " German silver, "
" " 4 " copper, silver "
" " 5 " German silver " "

When the shunt was in air, the effects—due to thermo-electric action arising from the slight differences in temperature in shunt itself previous to the passage of a current—were found to be of such a magnitude as to be negligible in a shunt of so high resistance as this one, although far too great to be permissible in a shunt of a resistance corresponding to those generally used. These thermal E.M.F.'s varied both in sign and amount from zero to 0·00 000 12 volt, and having as an extreme variation about 0·00 000 24 volts. In this respect the German silver leads were anywhere from two to five or more times as bad as the copper, and the too soft-soldered ones seemed to be best, although not enough so to make any marked difference in the readings, which were very small at most. The difference between the copper leads was not appreciable.

With the shunt in air I allowed various known currents to flow for five minutes, and then took several series of readings every quarter or half minute for about five minutes or longer, if necessary, to see what effect was produced in the shunt by the passage of the current. When the currents were only two or three amperes there was no effect produced large enough to notice; and as I could readily detect an E.M.F. greater than 0·00 000 04 volt the action, if any, must have been very small. With currents that produced a perceptible warming of the wire, I found a great variety of effects, differing even in the same set of leads at different times.

Curves were plotted, showing the effect produced by a current of 24·2 amperes in the shunt for five minutes. The sets of wires called No. 1 and No. 3 were made of the same piece of wire, and soldered at the same time with the same solder, and yet they vary in a very peculiar way, for which I have no explanation except that the composition of the German silver shunt has been acted upon by the solder used, and that in the short length (about 2in. near each end), where the soldered joints are, the metal is not homogeneous.

The greatest deflection shows the E.M.F. to have been 0·00 002 volt. Both sets of copper wires act in a similar manner, and give curves which rise quickly during the first half minute, and then gradually drop. Terminals No. 5 give a curve which begins high and falls sharply, and recovers slightly only to fall again. The curves of No. 3 fall rapidly at first, then rise in a regular and very marked manner, after which a fall takes place. Terminals No. 1 do not give especially marked curves unless it be on account of the much smaller deflections than any of the other wires.

I next placed the shunt in water, and examined it the next morning before passing any current through it, and found a large deflection of 105 units, corresponding to 0·00 004 2 volt. There was a slight difference between the various leads, generally about 5 per cent., but all deflections were in the same direction. I was careful to see that all parts of the shunt were under water, and that the soldered junctions were at nearly the same depth, but still the deflections remained. A current of 25 amperes was sent through the shunt to see if there would be a similar action to that when the shunt was in air, but upon connecting the galvanometer the deflection was entirely off the scale for five minutes, and lasted for an hour. I found that a current of less than an ampere in the shunt, but in the opposite direction, would reverse for a while the remains of the effect due to the 25 amperes. There was no apparent difference in the leads, and as the deflections were reversible by reversing the current, and always opposite to those produced directly by the current, I concluded that there was an electrolitic action caused by the current. The positive end of the shunt always turned black, and the negative end tended to become white. I found that by carefully timing duration and direction of currents, I could get a right deflection which would diminish and a left one begin, which would in turn give way to another right deflection, but I was not able to get four changes. With the soldered ends entirely out of water the actions were exactly the same; but the moment the *whole* shunt was out of water all action ceased, and the deflection became very small. Even 10in. of submerged wire gave the deflection, though to a lesser degree, as did also a wet rag wrapped around the wire for a short length.

A current of less than an ampere would produce less than 0·2 volt at the terminals, yet I could get these effects by it, so that simple decomposition of the water was not the cause of the trouble, which it seems to me must be attributed to a "polarization" effect. Having found the cause of the strange deflections when the shunt was in water, I did not continue the experiments any longer. The reason the large German silver shunt did not show such trouble is probably that it had been carefully shellaced when made, and was protected from the oxidising action.

In the light of these experiments, it seemed desirable to plan a shunt and galvanometer for use in comparing currents ranging from 1 to 1,000 amperes, which would not be affected by either thermal E.M.F.'s in its circuit or in the shunt itself. These data were assumed, and the galvanometer calculated.

Calibrating current to be 1 ampere.
Largest current to be 1,000 amperes.
Resistance of shunt to be 0·001 ohm.
E.M.F. at terminals when calibrating 0·001 volt.
Largest observed thermal E.M.F., 0·00 000 8 volt.
Average observed thermal E.M.F., about 0·00 000 08 volt.
Galvanometer current when calibrating to be less than 0·001 ampere.
Galvanometer coils to be 25 ohms of German silver wire.
Deflection to be 10 c.m. at 1·5 metres, or about 2deg.
Earth's field alone to be used.
Required dimensions of galvanometer.

The field due to the coils must be 0·006 in order to produce a deflection of 2deg. where H is 0·1717. The current producing this field would be 0·00 000 4 absolute unit; 25 ohms of No. 18 B. and S. German silver wire would be a length of 8,440 c.m.

$$\text{Then radius of coil} = \sqrt{\frac{8{,}440 \times 0{\cdot}00\ 000\ 4}{0{\cdot}006}} = 2.37 \text{ c.m.}$$

$$\text{Average length of a turn} = 2\pi r = 14{\cdot}9 \text{ c.m.}$$

$$\text{Number of turns} = \frac{l}{14{\cdot}9} = 566 \text{ or } 283 \text{ per spool.}$$

15 × 19 turns give a coil section 0·604 × 0·766in.

The galvanometer was made of a single copper casting, with two channels for the coils, 0·2in. apart. Each channel was 0·77in. deep, 0·61in. wide, and had an inside diameter of an inch. If the galvanometer is much lower than 25 ohms, the variable plug resistance of an ordinary bridge will cause an error too great to be safely neglected when only the galvanometer, leads, and plugs are in circuit. The reasons for the other numerical figures are almost self-evident. The shunt itself I would make of thin sheet German silver, with either copper or German silver end blocks, as was most convenient, but preferring copper. The lead wires to the galvanometer would be of copper, either soft or silver soldered to the end blocks, and should go to a commutator very near the shunt itself, and the galvanometer circuit so arranged as to be easily disconnected from the shunt and placed in a mercury cup to close the circuit for the resistance measurement. I would prefer to measure the total resistance by a standard bridge always connected and kept at a constant temperature.

This kind of a shunt could easily be made so that there would be very little heating, and if shellaced, or protected from oxidation in any other manner, could be used in water, although some kind of oil would probably be better.

There should be suitable mercury cups arranged so that the current could be easily and quickly reversed in the shunt, or the shunt entirely disconnected from the circuit.

THE PITTSBURG ELECTRIC RAILWAY.

A report has been presented to the Wall-street Ferry Electric Road Company by their consulting and supervising engineer, Mr. Howard Constable, which embodies some points which will be of interest to English engineers. The tramway is worked on the Bentley-Knight system, of which we gave some particulars and illustrations in our issue of February 24.

"The road is about 3¼ miles long. The first four blocks are double-tracked with grades of 3 per cent.; the next five blocks are single-tracked with grades up to 9 per cent., all laid with Johnson rails, dispensing with longitudinal stringers, and cable slot underground conduit. The rest of the road is single-tracked with overhead conductors, and is a succession of heavy curves and grades. There are some 25 curves of 40ft. radius and upwards, and some 36 varying grades, with scarcely any level track. Recently they have discovered that one of the grades is 12½ per cent. This was fortunately provided for by the good luck of having plenty of power.

"Altogether, the roadway presents a most severe test, and the great ease with which the cars take such grades is a most convincing proof of the capacity of electricity for this service, and sets at rest the grade question and many disputed points. The road is built and equipped on the Bentley-Knight system, and a very great deal of credit is due to those having the matter in charge for attempting such a piece of road, and for their perseverance in working it out successfully. Horse traction would be impossible on this line and cable impracticable, owing to the numerous curves.

"The power station is about a quarter of the way out on the road, and is equipped with one engine, four dynamos, and two boilers. The dynamos are coupled tandem, each rated at 250 volts, and would thus give on the line 500 volts. The observations made showed a voltage varying from 465 to 485. (The current at the car was not enough to kill a visiting electrician who laid his hand confidently upon the resistance-box, although it seemed to scare him a little. Possibly he was of that numerous class which Mr. Sprague recently referred to, as so far up in the clouds that no ground contact was made.)

"Natural gas is used under the boilers, and being such a wonderfully efficient and cheap fuel, the actual cost of operation is not a criterion for other places without a very carefully made analysis.

"The cars are equipped with motors on each axle, and the brushes are peculiarly free from sparking. The cars are also lighted by electricity.

"During the afternoon and Sunday traffic the cars ascend these heavy grades with loads varying from 50 to 75 passengers at a speed of 3½ to over four miles per hour. A rack and pinion is used on the heaviest grades, but for the summer the racks have been removed except on the heavy grades on the underground conduit division.

"The clogging up of the conduit has not proved to be a serious matter, and the troublesome switching of the overhead trollies has been done away with.

"There has been the usual long delay and experimenting to bring the work to perfection, but now the directors say they have decided to increase the rolling stock and extend the road over the bridge into Pittsburg. The long delays and expensive experimenting attendant upon adopting electricity on roads, greatly retard the cause of electric traction; but until the electric companies and railway men treat the whole question and the peculiar features of each road in a very different manner, there is little to hope of avoiding this difficulty."

Mr. Constable is an engineer who has had considerable experience with railway as well as with electrical work, and his remarks upon the question of tramway locomotion by means of electricity have a wide bearing. The experience of most electrical engineers up to the present has been gained in electric lighting installations, where the problems superimposed upon the electrical conditions are more nearly akin to those engaging the attention of marine engineers, or of mining engineers, on account of the condition of constant running requisite. In the case of electrical traction, however, it is to the railway engineer we shall have to look for the results of experience, and the cordial co-operation of successful railway men will probably be necessary before electric locomotion arrives at the perfection we all desire. This is not less true of road tramway work than of larger electric railways, and more progress will certainly be made if the preliminary details are put in the hands of those whose previous training enables them to see beforehand and provide against certain contingencies which, to them well known, would have to be bought by dear experience by electric traction experimenters.

LEGAL INTELLIGENCE.

Re GAULARD AND GIBBS' PATENT.

In the High Court of Justice (Chancery Division), before Mr. Justice Kekewich, judgment was given in this action on Monday last.

This was the hearing of a petition presented by Mr. Sebastian Ziani de Ferranti, an electrician, against Messrs. Lucian Gaulard, John Dixon Gibbs, and the National Company for the Distribution of Electricity by Secondary Generators, Limited, praying for the revocation of letters patent No. 4,362 of 1882. The letters patent were granted to Gaulard and Gibbs in respect of "a new system of distributing electricity for the production of light and power," consisting of the employment of an alternating current produced by an electro-dynamo machine, and determining, by its passage through a number of electrical generators of special construction, the formation of induced currents, of which the quality and the value depend only on the construction of the secondary coils of the electrical generators. The specification, as amended, goes on to say that "the currents generated under these conditions are utilised either by lamps to produce light, or by magneto machines to produce motive power." The petitioner described himself as "the patentee of many inventions in connection with the production, distribution and utilisation of electric currents, which inventions are now in extensive practical use," and stated in his petition that among other methods of distribution he for some time past had especially occupied himself with methods of effecting the same "by means of secondary generators by which electrical action is obtained at different points of an electrical circuit by means of electric induction only, without interrupting such circuit or making any connection with the conductor conveying the current." The petitioner also stated that in December, 1885, he invented an improved form of secondary generator for the purpose of effecting, economically and conveniently, the above-mentioned object, and that on December 9, 1885, he obtained provisional protection (No. 15,141 of 1885) for such invention, and had since filed a complete specification. The petitioner also stated that he had since manufactured and used secondary generators constructed according to his invention, the sale of which had recently been interfered with by the respondent company, which "claim to be entitled to restrain any person using any mode of electrical distribution by means of secondary generators, of whatever form or construction such generators may be." The petitioner said the invention patented by Gaulard and Gibbs was in nowise novel, and that the letters patent were invalid on this and other grounds; that the existence of the letters patent claiming a wide and general monopoly of the system of distribution by means of secondary generators which was known to and the property of the public at the date of the letters patent had been and was of great injury to the public by preventing the sale of machines made according to the petitioner's invention, as well as those made by other inventors; and that "the public are prejudiced by the above-mentioned general claim in the said letters patent, because consumers of electricity are not in general acquainted with the science of electricity and the technical application thereof, and are therefore unable to form an opinion as to the invalidity of the said letters patent, whereby the sale and use of improved secondary generators are wholly prevented."

Sir Henry James, Q.C., Mr. Aston, Q.C., Mr. J. C. Graham, and Mr. P. H. Lawrence were for the respondents; and Sir Horace Davey, Q.C., Mr. Moulton, Q.C., and Mr. L. E. Pyke for the petitioner.

Mr. Justice Kekewich, in delivering judgment, after referring, on the question of non-conformity of the complete with the provisional specification, to the observations of Lord Blackburn in "Bailey *v.* Roberton" ("L.R." 3, App. Cas., 1,055), said that the amendment of the complete specification had the effect of substituting the specification in its present form for the original; but in its amended form it must comply with the provisions of the law, including those as to conformity with the provisional specification, as explained in "Bailey *v.* Roberton." The provisional specification in the present case spoke of "an unlimited number of induction coils," whereas the complete specification spoke of "a number" only. Was this an essential difference? His Lordship decided this question in the negative. One passage of the provisional specification was as follows:—"When an electric current approaches or recedes from a circuit of selenoidical form, it determines in this latter a current of induction without in any way modifying the value of the primary current." It had been said that the provisional specification depended on the statement "without in any way modifying the value of the primary current," and that this was false and was abandoned in the complete specification. His Lordship continued as follows:—That it is false is conceded, and for the present purpose it may be assumed that it is abandoned in the complete specification, but I do not think that fact is fatal to the patent. It may be important as regards utility and relevant on the question of novelty, but it does not establish nonconformity between the two documents. The most that can be said is that the provisional specification contains, but the complete one omits, an erroneous statement respecting the patented invention which, if scientifically true, would add greatly to its value. That to my mind is not enough. But it is said that, whereas the provisional specification rests the invention on induction coils of a special construction, the complete specification as amended applies it to induction coils of every character, and this makes the latter different in the sense of being more extensive. This is a formidable objection if true. The foundation of it is the abandonment of the claim for special construction. But the patentee, though he has done this—though he has said, "I do not claim to have any special form of induction coil"—has retained, as part of his combination, the use of those of a special construction. He does not claim to construct, but he requires to use certain instruments, and those only when constructed. What is the effect of this on the complete specification standing alone is another question, but on the question of conformity I hold there is no such difference as is alleged between the two documents. Each asserts the necessity for a

Digitized by Google

secondary generator of a special construction. So far, I have dealt with mere questions of language, so as to enable the Court to read the documents for the above purpose. In further examining the specification (and henceforward I deal with the complete one only) one depends much on evidence. There are still questions of construction to be solved, but evidence is required not only to explain terms of art, but to prove what was known at the date of the patent. I may mention here one objection, out of order, to get rid of it. It has been stated by the patentee (Gibbs) that the invention is not thoroughly successful unless there is an equal mass of metal in the primary and secondary wires, and it is urged that, whether true or not—which is said to be immaterial—this ought to have been in the specification. If true, it might, with advantage, have been stated; but it only comes to this—that what is possible with unequal masses, and is more feasible as you approach equality, can only be made a thorough commercial success when that equality is practically attained. I do not think that the omission to make such a statement can defeat the patent. Another objection urged respecting secondary generators was that a divided core is essential, and that this is not stated. It is, without doubt, stated as regards the first, and the evidence has satisfied me that it is sufficiently implied in the language describing the second, and, further, that no electrician would stop to inquire whether a solid or divided core is intended. But, putting aside these two objections to the description of secondary generators, and assuming, of course, the soundness of my view that they are of special construction, how does the specification stand as regards the information given for their selection? And, in order to get an answer to this question, first consider what information is reasonably required? A patentee is bound to tell the public in his specification, not only what his invention is, but how practical effect is to be given to it, and if the invention be a machine, how that machine can be manufactured. I have paraphrased the statute. If there are many different ways of effecting the entire object, or any particular part of it, he is not bound to specify them all in detail, but he is bound to give such instances—selections it may be, from a class—as will enable a competent workman to know what he ought to use. And he is further bound to refer to these instances, or the class from which they come, in language which leaves no doubt what articles are and what are not applicable to the production of the intended result. This is important for two reasons—first, in return for his monopoly, a patentee is bound to put the public in possession, as far as description can do it, of his invention in principle and detail; and, secondly, as a condition of being entitled to restrain other operators from producing his result by the same means, he is bound to tell them precisely what they cannot do except under penalty of an injunction with its serious consequences, and thus to indicate what can be done safely. This is not less true where the patent is for a combination than in any other case. Indeed, I am not sure that the obligation ought not, in such a case, to be particularly strict. If a man says, "I claim to have protected, as my invention, three things combined which, though separately well known, have not been before used together," it is reasonable and right that he should state exactly what each of those three things is; and if anyone of them belongs to a class, comprehending several varieties, then also which of the varieties are intended. And this, of course, he can easily do, as, admittedly, the combined items are well known. What is the combination, several times described, with some variation of language, but none of substance? Take it from Mr. Aston's statement to his own witness Dr. Hopkinson. The combined elements are three in number—(1) an alternating dynamo supplying a main wire; (2) a current in that wire of high tension; (3) a secondary generator such as is described. The description there mentioned is that of the witness, but of course he could only explain or illustrate—he could not go beyond the specification. In passing, let me observe that I am not satisfied that there are really three elements, but I will not dwell on this. Let it be assumed for the present purpose that there are three items, the alternating dynamo, the high tension, and the secondary generators described in the specificaion. There is no difficulty about the first or second, but how has the patentee fulfilled his obligations as regards the third? It is conclusively proved by the petitioners, and not denied by the respondents, that there is nothing special about the secondary generators described, that they differ from others of their class only in unessential details, and that any other instrument of the class—induction coils with divided core—would answer the purpose equally well. So completely is this admitted by the respondents that they contest the conclusion that a special construction is intended. No more about that. Is it reasonable to hold that the divided core is the special construction? I think not. It would, to my mind, be pressing the maxim *ut res valeat* too severely to construe the words "electrical generators of special construction" to mean those belonging to one of two well-known and exhaustive classes, especially when one finds no reference to that class as a whole, but an elaborate description of two particular specimens. If the intention had been to refer to electrical generators having a divided core, that might have been easily done in a single line, and the examples would have been needless and out of place. Then it is urged that the special construction refers to the diminution of tension to those which, receiving an electric current of high tension, pass it on as a current of low tension. It is not pretended that this is said in so many words; no counsel or witness has ventured to put his finger on an expression which states plainly that the secondary generator employed must be of what is styled the "step-down" character. It is conceded that no other will do, and it may be assumed that no other would be attempted by a competent workman, but this is because of a well-known scientific fact, and not because of information given by the patentee. There is no occasion to examine the provisional specification on this point or to inquire whether the complete specification in its original form is agreeable to the view now taken of it as amended. I hold that, as amended, it does not say one of the elements of the combination is a step-down induction coil. That is what you are to use with an alternating dynamo and a high-tension primary wire, in order to produce the desired result. Nothing less than this would suffice. It is not enough to say, as the patentee does, that the quality and value of the induced currents depend on the special construction of the electrical generators without giving a plain statement in what the special construction consists. It is not suggested that the examples are exhaustive of the class of machines which would answer its purpose. I think that a manufacturer is placed by this specification in a difficulty. He knows, of course, that he cannot use either of the induction coils described, but if he wishes to use one of the same class, but differing in detail, he cannot ascertain from the specification whether he may safely do so or not Changing the phrase, the patentee has not in his complete specification ascertained the nature of his invention, and how it is to be performed, in that he has not explained what constitutes the third item in his combination. Mr. Aston says, of course, the use of equivalents would be an infringement, but I do not think that doctrine can be called in aid of a patent which professedly rests on a special construction. In its original form, the specification claimed the special construction of the secondary generators required to produce the desired result. Apart from any question respecting conformity with the provisional specification, the patent could then have been supported, so far as language was concerned; but the patentee was driven to abandon this part of the claim and to amend by way of disclaimer. This was a difficult task. I am disposed to think that it could not have been performed without destroying the patent—could not, that is, have been so performed as to leave a supportable residue. But, whatever was possible, I hold that it has not been done, and that, with the abandonment of the third item of claim, the whole specification falls to the ground. This holding makes it unnecessary to go into the question of anticipation. The evidence on this point is conflicting, and I have the testimony of men of acknowledged eminence and truthfulness on either side. Besides this, there are many documents, and the criticism of them has been long and minute. Before pronouncing a deliberate opinion on the question, I should be obliged again to examine those documents by the light of the evidence, which would have to be reperused for the purpose, and of the arguments, which would have to be recalled and weighed with regard both to documents and evidence. I do not consider myself called upon to do this; but it may be convenient for me to state what, subject to such revision as I have just mentioned, is the result of my best attention during the trial. I do not question—nobody could successfully question—the accuracy of Mr. Aston's distinction between anticipation by documents only—what is sometimes called paper anticipation—and that by manufacture or use. It is grounded on common sense and established by the authorities to which he referred and many others. Guides for the application of the distinction are also to be found in those cases, and notably in the judgment of Lord Westbury, which Mr. Aston quoted. But the distinction concedes that there may be a paper anticipation, and the question here seems to be whether the documents which have been referred to did not separately or together add so much to the stock of common knowledge that nothing remained for invention within the limits of Messrs. Gaulard and Gibbs's specification. Mr. Aston observed that about the years 1878-9 there was an avalanche of patents, and he accepted my suggestion that many inventors were buried in it. He did not pursue the analogy further, and perhaps forgot that a congealed mass has a law of motion of its own, which after a time again brings to light, capable of recognition, though it cannot revivify, buried limbs. So here science has progressed, and in its progress has again called attention to discoveries of bygone years, long buried and forgotten, and of which Sir William Thomson was in 1881 either ignorant or oblivious. Being brought to light, they are recognised as bearing a striking resemblance to others since called into existence, and there is at least some ground for arguing that there is no substantial difference between the past and present. There is often a genuine and complete answer to an argument of that kind. Why, says the patentee of later date, why was not this old invention put in practice if, as you say, it anticipated mine, which has been proved to have been feasible and useful? It is frequently difficult—it is some times impossible—to give a satisfactory reply to such an objection, but I think that Sir William Thomson gave one in this case. He says that at that time, the period of those numerous patents, there was no demand for electric lighting—no encouragement, that is, for inventors to persevere and put their inventions in practice. That would scarcely have sufficed; but he added, in effect, that there was not then known any lamp to which those inventions could be usefully applied, that failing any such lamp they necessarily slumbered, but that, such a lamp having been now discovered, their character and value are apparent. That reply, to my mind, detracts largely from the force of the objection to which I have referred. As at present advised, I fail to see how Messrs. Gaulard and Gibbs made any discovery in the technical sense of the word, or, rather, what they published to the world which was not already disclosed by some one or more of the earlier specifications. As I do not propose to examine any of them in detail, I will not mention more than one, which was not, I think, the one mostly relied on by the petitioner, and possibly is not the best example. I refer to the specification of C. W. Harrison of March 1, 1879. You cannot, it seems, take his description of the third part of his invention any more than you can take any other of the specifications and therefrom build a complete machine according to Messrs. Gaulard and Gibbs' patent—that is, some ingenuity would be required to supplement the directions given. But are not all the necessary directions given? Do they not all concern well-known tools capable of producing well-known effects; and are they not combined precisely as Messrs. Gaulard and Gibbs combine them. Mr. Aston's answer is that the secondary generator was employed to alter the tension, not by diminution, but by increase; not by stepping down—to adopt his favourite expression—but by stepping up. This may be true; but it was common knowledge that an induction coil might be used for alteration in either direction, and the application of it in one way instead of the other cannot be

Digitized by Google

deemed invention. Again, Messrs. Gaulard and Gibbs' patent may have taught the electrical world for the first time that high tension in the primary wire is essential to successful work—in other words, that they have discovered that the best, if not the only useful, mode of using the dynamo for electric lighting is by the creation of high tension. If so, they are entitled to credit for having first seen what other labourers in the same field have failed to see, but ascertaining the best use of a known tool does not fall within the proper definition of invention. The reasons which have prompted me to dispose of this case at once on the point on which I have come to a definite conclusion, and not further to consider those requiring further consideration if my judgment were to be rested on them, render it also unnecessary to deal with the question of utility, but on that I have formed a definite opinion, and it is better that I should express it. Having regard to the great and rapid advance made in this particular branch of science during the last few years, one would expect an invention of 1882 to have been ere this improved upon, if not superseded, and it is not surprising, nor is it any discredit to Messrs. Gaulard and Gibb's ingenuity, to hear that arrangements on the parallel system are found to be far more effective than those on the series system adopted by the patentees. The evidence indicated, if it did not prove, that the latter would soon give way, if it has not already given way, to the former. On the other hand, I have sufficient evidence that the series system has been successful—not only tried, but used and found to work with at least a large measure of success. If, therefore, I could hold the patent to be good on other ground, I certainly should not hold it to be bad on the point of utility. For the reasons which I have given I am of opinion that what Messrs. Gaulard and Gibbs describe in their amended specification as their invention, and for which they claim a monopoly, is not the proper subject matter of a patent, that, therefore, the patent granted to them ought to be revoked, and I must make an order for revocation as asked by the petitioner. The respondents must pay the costs, to be taxed on the higher scale.

NEW COMPANIES REGISTERED.

Companies of the Month.—The following electrical companies have been registered during the past month:—

D'Humy Cabinet Battery Syndicate, £250 shares	£15,000
The *Electrician* Printing and Publishing Company, £10 shares	10,000
Buckingham Electric Light and Power Supply, £1 shares	5,000
Electrical Purification Company, £1 shares	15,000
Luther, Hanson and Co., £5 shares	7,500
Petroleum Engine Company of America, £5 shares	150,000
Westminster Electric Light Supply Corporation, £5 shares	100,000
Automatic Electrical Corporation, £20 shares	75,000
International Engineering, £1 shares	5,000
J. and J. Charlesworth, £100 shares	500,000

Westminster Electric Supply Corporation, Limited.—Registered by Linklater and Company, 2, Bond-court, Walbrook. The nominal capital of the Company is £100,000 in shares of £5 each, of which 100 shall be founders' shares, and the remaining 19,900 shall be ordinary shares. Object: to carry on either in the city of Westminster or elsewhere the trade or business of electric lighting. The first subscribers are:—

	Founders' shares.
J. B. Martin, 2, Victoria-mansions, Westminster	1
Sir J. B. Heron-Maxwell, Carlton Club, Pall Mall	1
R. W. Wallace, 2, Harcourt-buildings, Piccadilly	1
J. W. Hiscox, 8, Victoria-street, Westminster	1
W. H. Baker, 74, Vincent-square, S.W.	1
H. Kimber, York-street, Westminster	1
H. A. Hunt, jun., 43, Parliament-street, S.W.	1

The Directors shall not be less than three nor more than seven in number, and the first Directors shall be H. Kimber, Joseph Browne Martin, and Roger William Wallace, and any other persons as the Board shall at any time before the ordinary meeting of the Company in the year 1891 appoint to be Directors, provided that the number of Directors shall not exceed seven in the whole. The remuneration of the Board of Directors shall be £200 per annum to the Chairman of the Board, and £100 per annum to each of the other Directors, and such other sum (if any) as shall be voted by the Company in general meeting.

CITY NOTES.

Removal.—Mr. C. Langdon Davies has removed from 110, Cannon-street, E.C., to Mowbray House, Victoria Embankment, W.C.

Brazilian Submarine Telegraph Company.—The traffic receipts of the Brazilian Submarine Telegraph Company, Limited, for the week ending July 6 amounted to £4,740.

Great Northern Telegraph Company.—The Great Northern Company's telegraph receipts for June were £23,000, making, from January 1 to June 30, £132,000, against £127,120 in 1887, and £124,560 in 1886.

West Coast of America Telegraph Company.—At the last Board meeting the Directors of the West Coast of America Telegraph Company, Limited, declared an interim dividend of 4s. per share, free of income-tax, in respect of the first half of 1888, payable the 23rd inst.

Western Brazilian Telegraph Company.—The traffic receipts of the Western Brazilian Telegraph Company, Limited, for the week ended July 6, after deducting the "fifth" of the gross receipts payable to the London-Platino Brazilian Telegraph Company, Limited, amounted to £3,958.

Direct United States Cable Company.—The Directors of the Direct United States Cable Company, Limited, recommend a final dividend of 2s. per share, tax free, payable on and after the 21st July, making, with the interim dividends already paid, 2 per cent. for the year ending June 30. Recourse will, it is stated, be had to the reserve fund account to make up the required amount for such dividend.

Eastern Telegraph Company.—The Eastern Telegraph Company, Limited, announce that, subject to final audit, the accounts show, after placing about £75,000 to reserve fund, a balance available for dividend sufficient to pay at the general meeting on July 19 next the fixed dividend of 3s. per share, being at the rate of 6 per cent. per annum on the preference shares, and a final dividend of 2s. 6d. per share, with a bonus of 2s. per share, free of income-tax, on the ordinary shares, making, with previous payments on account, a total of 6 per cent. per annum on those shares for the year ended March 31, 1888.

Greenwood and Batley, Limited.—The company is formed to acquire the business of Messrs. Greenwood and Batley, engineers and machine-makers, of the Albion Works, Leeds, and to carry on in the United Kingdom and elsewhere the trade or business of mechanical, hydraulic, electrical, and general engineers; machine, engine, and tool makers, iron and brass founders, metal workers, millwrights, boiler-makers, steel converters, colliery owners, metallurgists, manufacturing chemists, shipbuilders and shipowners, and carriers by land or water; and to buy, sell, manufacture, repair, convert, let on hire, and deal in machinery, apparatus for making machinery, rolling stock, steamers, ships, iron, steel, metals, metal implements, tools, utensils, and plant, and conveniences of all kinds.

West African Telegraph Company.—The report of the Directors of the West African Telegraph Company, Limited, for the year ended December 31, 1887, states that the gross receipts, including the balance brought down from last account (£128), amount to £55,268, the general expenditure being £21,586; leaving a balance of £33,682. After providing for debenture interest paid and accrued, £10,000 has been carried to repairs and renewal account, and it has also been considered advisable to write down the preliminary expenses by £500. The Directors propose to carry £3,500 to a debenture redemption account, and recommend the payment of a dividend of 3s. per share, free of income-tax, leaving £1,215 to be carried forward to the current year's account. The Directors are glad to report that since the repair the São Thomé-Loanda section has given no cause for anxiety.

PROVISIONAL PATENTS, 1888.

JUNE 29.

9487. **Improvements in electrical instruments.** Frederick Lawrence Rawson and William White, 11, Queen Victoria-street, London, E.C.

9501. **An improved screw grip for adjustable lamp and other standards, and for electric pendent lamps.** William Arthur Smith Benson, John Lovegrove, and Elie Hinton, trading as W. A. S. Benson and Co., 82, New Bond-street London, W. (Complete specification.)

9503. **Improvements in and relating to steam and other motive-power engines.** John Cole Chapman, 70, Chancery-lane London, W.C.

9504. **Improvements in and relating to steam and other motive-power engines.** John Cole Chapman, 70, Chancery-lane, London, W.C.

9508. **Improvements in and relating to telegraphing apparatus used on board ship.** William France and Robert Morgan, 77, Chancery-lane, London, W.C.

JUNE 30.

9547. **Improvements in electric motors and cars or carriages therefor.** Richard Richardson Hutchinson, 4, Little Moorfields, London, E.C.

9553. **Improvements in adjustable electrical lighting devices.** Alexander Leslie Fyfe and John Main, 22, Southampton-buildings, Chancery-lane, W.C., Middlesex.

JULY 2.

9584. **Improvements in galvanic batteries for electric lighting and other purposes.** Samuel Miller, 1, Langton Cottages, Melbourne-square, Brixton-road, S.W.

9588. **Improvements connected with electrical appliances for lighting trains, with automatic connection between the carriages.** Friedrich Georg Oberdorfer and Julius Neu, 166, Fleet-street, London.

9595. **Improvements in machinery or apparatus for generating electricity and in electro-motors.** William Henry Allen and Richard Wright, 35, Southampton-buildings, London, W.C.

9615. **Improvement in mounting incandescent electric lamps.** George Henry Rayner, 43, Southampton-buildings, Middlesex. (Julen Ragonet, Paris.)

Digitized by Google

JULY 3.

9660. **Improvements in electric motors and dynamo machines.** Alfred Julius Boult, 323, High Holborn, Middlesex. (Orazio Lugo, United States.) (Complete specification.)

9661. **Improvements in telephone transmitters.** Alfred Julius Boult, 323, High Holborn, Middlesex. (Julius Emner, Junior, United States.) (Complete specification.)

9662. **Improvements in or relating to electrical type-writers.** Alfred Julius Boult, 323, High Holborn, Middlesex. (James Francis McLaughlin, United States.) (Complete specification.)

9672. **Improvements in dynamo-electric machines and electro-motors.** Grosvenor Porter Lowrey, George Frederick Seward, and Thomas Leopold Willson, 169, Fleet-street, London.

JULY 4.

9693. **Improvements in the manufacture of wire for telegraphic and other purposes.** John Edward Tenison Wood, 40, Grove Hill-road, Camberwell, Surrey.

9708. **The telephonograph.** Gerard Huck, 72, St. James'-street, Burnley, Lancashire.

9730. **An improved cut-out for electric circuits.** William Hopkin Akester and George Hopkins, 57, Chancery-lane, London.

9745. **An improved system for driving moving electric motors or locomotives in series.** Edward Manville, 1, Queen-Victoria-street, London, E.C.

9747. **Improvements in electric bells.** Leslie Watt Winnall, 4, South-street, Finsbury, London.

9759. **A self-acting dynamic machine.** Johann Papiesz, 142, Fleet-street, London.

JULY 5.

9785. **An improved motor.** Isaac Watts and Henry George Gullick, Bristol Bank Buildings, Bristol.

9808. **Electrical fountains.** Joseph Percy Barralet, Sydney-road, Colney Hatch, Middlesex.

COMPLETE SPECIFICATIONS ACCEPTED.

MARCH 26, 1887.

4533. **Improvements in electric locomotives and vehicles.** Michael Radcliffe Ward, 4th Floor, 55, Chancery-lane, London, W.C.

AUGUST 5, 1887.

10,767. **Improvements in instruments for measuring electric currents, and for regulating and controlling dynamo-electric machines and prime movers.** William Lowrie, Charles James Hall, and Harold Werner Kolle, 433, Strand, London.

AUGUST 30, 1887.

11,751. **Improvements in electrical signalling apparatus for railways.** Arthur Edward Nicholl, 54, Fleet-street, London, E.C.

SEPTEMBER 1, 1887.

11,853. **Flexible supports for telegraph or other wires.** Frank Caws, Suffolk House, Lawrence Pountney-hill, E.C.

SEPTEMBER 2, 1887.

11,932. **Improved means for making and insulating the joints or connections of electrical conducting cables.** Charles Denton Abel, 28, Southampton-buildings, Chancery-lane, London, W.C. (Siemens and Halske, Germany.)

SEPTEMBER 3, 1887.

11,950. **Improvements in electrical telephones.** John Samuel Ross and Henry Baines, 15, Gunterstone-road, West Kensington, S.W.

SEPTEMBER 5, 1887.

12,025. **Improvements in apparatus for operating or controlling type-writers, type-setting machines and the like by the aid of electricity.** Edward Fitzgerald Law, 45, Southampton-buildings, London.

DECEMBER 1, 1887.

16,554. **A new or improved electric apparatus for indicating distant water level and similar purposes.** Gustav Binter, 18, Buckingham-street, Strand, London.

FEBRUARY 9, 1888.

1968. **Improved secondary battery or accumulator for the storage of electricity.** Walter Tilley, 11, Lewes road, Brighton.

APRIL 17, 1888.

5731. **Improvements in and relating to apparatus for measuring electric currents, which apparatus will also serve as a motor.** Henry Harris Lake, 45, Southampton-buildings, London. (Elihu Thomson, United States.)

5732. **Improvements in and relating to apparatus for measuring electric currents, which apparatus will also serve as a motor.** Henry Harris Lake, 45, Southampton-buildings, London. (Elihu Thomson, United States.)

APRIL 25, 1888.

6157. **Improvements in lanterns for electric arc lamps, and in posts or columns for supporting the same.** Richard Edwd. Keen, 45, Southampton-buildings, London, W.C.

MAY 22, 1888.

7541. **Improvements in dynamo electric generators or motors.** William Phillips Thompson, 6, Lord-street, Liverpool. (Henry W. Spang, United States.)

7551. **Improvements in coupling devices for electrical and other purposes, and in indicators to be used in conjunction therewith.** John Kendall and Owen Cooper, 45, Southampton-buildings, London, W.C.

MAY 29, 1888.

7850. **Improvements in or relating to alternate current electric distribution.** William Phillips Thompson, 6, Lord-street, Liverpool. (George Westinghouse, Junior, United States.)

MAY 31, 1888.

7977. **Improvements in the mode of filling secondary battery plates.** Henry Gurney Morris and Pedro Grotjan Salom, 320, High Holborn, London, W.C.

JUNE 5, 1888.

8171. **Improvements in magneto-electric liquid level indicators.** John Joseph Ghegan, 52, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1887.

8701. **Producing electric energy for lighting, &c.** J. Ross. 8d.

10,701. **Electric incandescence lamps.** W. B. Sayers and W. H. Sturge. 8d.

10,740. **Regulators for electric lamps.** S. Mathis. 8d.

NOTES.

Pekin.—The Emperor of China is having electric lights fixed up in his palace grounds at Pekin at a cost of £1,400.

Parliamentary.—In the House of Lords, on Monday, the Electric Lighting Order Confirmation Bill was read a second time.

Telegraphs to Australia.—We are informed by the Post Office authorities that telegraphic communication with Australia and beyond is now restored.

The New Filament.—The wonderful filament submitted to Mr. Westinghouse, invented by a Russian, we are given to understand was that of the Khotinsky lamp.

Eiffel Tower.—It was proposed to work one of the lifts at the Eiffel Tower in Paris by an electro-motor, but we understand that for some reason the idea has been abandoned.

Electric Tramway for Milan.—The Omnibus Company of Milan have appointed a commission to go into the prospect of establishing an electric tramway between Milan and Monza.

Bootle (Lancs.).—At a meeting of the Bootle Town Council, on Wednesday, it was agreed to sign a memorial to the Postmaster of Liverpool, asking for increased telegraphic accommodation.

Electric Lighting in Paris.—The larger portion of the work of fitting the Salles des Fêtes of the Hotel de Ville, at Paris, with electric lights has been carried out, and gas will soon be completely ousted.

Julien Company.—The announcement is made that the Julien Electric Company have declared a semi-annual dividend of 2½ per cent. This is taken as a sign of the growing demand for storage batteries in America.

Bothers the Astronomers.—The arc lights at Detroit are so often reflected on the clouds, causing an effect like that of the moon, that they interfere with astronomical observations, and the astronomers have to wait very late until they are put out.

Sunday Telephone.—On Sunday last the telephone was working for the first time in London on the Sabbath. It will now continue to be available night and day for all subscribers who require to use it. It will be available when the telephone offices are closed.

What the Natchez (U.S.) Gas Company Says.—In their report the directors say: "This company, instead of enlarging ther gas plant to meet any growing demand for nocturnal uses, wisely propose to enlarge the scope of their work by adding an electric light plant."

The Lightning Gave the Alarm.—On Sunday night the Metropolitan Fire Brigade turned out in the fierce and pouring wet in answer to the fire alarm. It was found eventually, however, that it was merely a freak of the lightning, the alarm being probably given by inductive effect.

London Bridge.—The plant for central-station lighting at London Bridge, mentioned last week as being started by Messrs. Beaumont and Kent, is being installed for Mr. John Kent, A.M.S.T.E., principal of the College of Electrical Engineering, Railway-approach, for whom Mr. F. J. Beaumont is engineer.

The Pilsen-Joel Company.—As will be seen in our advertisement columns, the Pilsen-Joel Company invite tenders from capitalists or companies to take over the whole of their patents, together with the works of the company, as a going concern, and their central lighting stations, which are capable of large extension.

Electric Execution.—"Electranged" is the title given in New York to the method of execution by electricity. It is thought doubtful, after all, whether it will be adopted. The result of the experiment has caused a reaction against it. Edison, it is said, by the way, recommends that the criminal be handcuffed and electric wire fastened to the handcuffs.

Personal.—We must congratulate Messrs. Woodhouse and Rawson, Limited, on having obtained the services of Mr. Antony Reckenzaun as manager of their works at Cadby Hall. Mr. Reckenzaun has also been appointed as managing engineer to a company which Messrs. Woodhouse and Rawson, Limited, are forming for the application of electricity to locomotion and transmission of power.

Quick Work.—The Heisler system has been adopted at Hackettstown, N.J., for street and commercial lighting, and a plant has been erected by Messrs. White and Rusling, agents for the company, of 137, Broadway, N.Y. The contract was signed and the order sent for the electrical appliances on May 1, and the apparatus was tested and the lights turned on for the first time on June 2, which is putting up a plant on pretty short notice.

Hell Gate Tower Sold for Scrap.—The Hell Gate electric tower has just been sold for 125dols. It is only a little more than two years ago that the tower was erected at a cost of 14,500dols., but the light proved a failure. It was found that it threw shadows across the surface of the water, which made navigation dangerous. The mariners petitioned the Government to extinguish the light, which the Government did at midnight 1st December, 1887.

Medical Electricity.—The Directors of the Institute of Medical Electricity, Limited, have taken commodious premises at 24a, Regent-street, with side entrance in Jermyn-street, and are having them fitted with the latest and best appliances for electrical treatment by all known methods, including the "Electrified Room" system, which has been approved so highly by medical men at Southsea. It is expected that the establishment will be opened in a few weeks.

Strand.—Last week at the meeting of the Strand District Board of Works, the following notices of intended application for provisional orders to supply electricity for lighting were reported as received—viz.: from the South Metropolitan Electric Supply Company, the Electrical Power Storage Company, London Electric Supply Corporation, the Westminster Electric Supply Corporation, and Messrs. Walter F. Glover and Co. These were referred to the Lighting Committee for consideration and report.

Strange Recovery of Eyesight.—A Wolverhampton paper states that during the heavy thunderstorm of Tuesday a collier, named Bates, who had lost his sight through an accident, was being led home, when a flash of lightning was reflected on the spectacles he was wearing to conceal his disfigurement. After the peal of thunder which followed he complained of pain in his head. The next moment, to his surprise, he found that he had regained possession of his eyesight. The occurrence has caused considerable excitement in the locality.

Bournemouth.—At the last meeting of the Lighting Committee of the Town Council a letter was read from Mr.

Digitized by Google

Sidney Morse, enclosing a notice of intention to apply for a provisional order under the Electric Lighting Act, 1882, to authorise Messrs. Walter T. Glover and Co., or a company to be formed for the purpose, to supply electricity within the area of the Urban Sanitary Authority of Bournemouth. A letter was also read from the secretary of the Bournemouth Electric Light and Power Co., setting forth the objects of that company. It was decided merely to acknowledge the letters.

Ornithological.—Two sparrows have hatched a brood of young ones under the dome of the electric bell at Hook Station, on the main line of the L. and S. W. R. As this bell gives warning of the approach of all passenger trains, whether they set down at Hook or run through, it is rung very frequently during the day, and one would hardly have supposed when the birds found that they had selected this curious and somewhat noisy nesting place, that they would persevere in their intentions. The nest occupies the space between the top of the box containing the electro-magnets and the dome.

Italian Exhibition.—With reference to our article last week, Messrs. Laing, Wharton, and Down write pointing out that the installation at Peter Robinson's, consisting of 80 arcs and 400 incandescents (even when increased to 700, and with accumulators for 100 thrown in) can hardly be considered "nearly equal" to that at the Italian Exhibition, where they are running 315 10 ampere arcs, and 300 incandescents. They also indicate that the remark that when arc lamps are run in series not more than four or five lamps can conveniently be turned off from the circuit does not apply to the Thomson-Houston system.

Uses for Motors.—On the Comstock, in America, the new Nevada Mills will be run with electric motors, through a five-eighth copper cable, driving 60 stamps. For Silver City, Idaho, a Sprague electric plant is used at a mine to drive a 50 stamp mill four miles away from a waterfall, and the same manufacturers have recently received an order for an electric plant to be used in training and elevating the guns on the new United States cruiser "Chicago." We hear also of an iron company in the South thinking of running dynamos by means of waste heat at the furnace to drive pumps several miles away.

Sweden.—Electric lighting has been successfully tried on the Skane-Holland Railway, in Sweden, where a train was despatched from Helsingborg, fitted with electric light in all the carriages except one, so as to demonstrate its superiority. There were altogether 17 incandescent lamps in use, fed from an accumulator in the luggage van. The light was very good and steady, and all the lamps could be lighted or extinguished in a moment. The installation has been effected by Messrs. Edwin Audrén and Co., Gothenburg, and it is the intention to fit all the express trains between Christiania and Helsingborg with the electric light.

Electric Light from the Tide.—It is proposed to light the rising watering place of Sullivan Harbour, Maine, U.S., by means of electricity by utilising the tide. Both arc and incandescent lamps will be required, and it is proposed to utilise the currents, which run for four hours either way on each tide through a narrow gorge within fifteen hundred feet of the village street. Its tide waters fill an immense arm of the sea, which runs up for three or four miles behind the village, and thousands of horse-power goes to waste, which it is now proposed to use, and by means of dynamos run by water wheels, and auxiliary storage batteries, light up the district.

Richmond.—At the Vestry meeting on July 4, the vestry clerk read a letter from the West Middlesex Electric Lighting Company, Limited, Caxton House, The Grove, Hammersmith, W., giving notice that it is the intention of the company to apply, on or before the 21st December next, to the Board of Trade for a Provisional Order authorising them to supply electricity for public and private lighting and other purposes within the area of the Board. It was suggested that the letter should be referred to the General Purposes Committee, as there were not so many directors of the gas company on that; but it was finally referred to the Parliamentary Committee, as being composed of gentlemen who thoroughly understood the meaning of intended Bills.

Public Supply at Bradford.—With reference to the circular recently issued by the Bradford Corporation, particulars of which we gave last week, we may point out, with regard to the alternative method of lighting, that experience has shown that for restaurants, cellars, and offices below surface, and in other positions where gas is almost constantly used, the charge of £1 (or even of £2) each lamp per year often offers a very great saving over gas burnt continually; whereas those customers who usually light up at dusk and close at six naturally object to pay an equal sum to the long-hour consumer. To them the meter rate of 5d. a unit will be little, if any, increase on the gas bills. If the Corporation can keep up these two alternative methods of charging there will result a great impetus in the extension of electric lighting in that neighbourhood.

They Just Live on the Cars.—"Every little town in Southern California is just ring-streaked and striped with street car lines. Street cars and cement sidewalks—the nicest sidewalks in the world—why, they lay them away out into the country. A town of 2,500 people out here without street cars, electric lights and suburbs would be as great a rarity as a leopard or a coach dog without spots. There is an electric motor car in San Diego running out to University Heights. Coming into the city down the long hills—talk about speed. You just hold your breath and try to think of the prayer you should have said when you got out of bed. A runaway horse on a thirty day note couldn't keep in sight of one of those cars coming down the grade. One thing, rents are so fearfully high, and houses are so hard to get out here, that I suppose a good many people just about live in the street cars, and that makes the lines pay. They do seem to pay, and on five cent fare, too".—*Burdette.*

Electric Firing.—Since safe explosives and water-shields have come into use, says Mr. Geo. S. André, F.G.S., in the *Colliery Guardian*, electric firing has assumed a degree of importance it had not before. Electric ignition has become a necessity. Hitherto the machines employed for generating the electric current, or the electric discharge by means of which the fuses are ignited, have failed to satisfy all the conditions of underground blasting. Frictional machines are uncertain, and the magneto-exploders in common use leave much to be desired. A French electrician of repute, M. Ducretet, has devised a machine for firing purposes on the lines of the well-known Breguet exploder, which promises to satisfy every condition. It is simple, light, well protected, and very effective where the number of shots to be fired simultaneously is not large. By an ingenious arrangement it is made to register the intensity of the spark, and also to pass a testing current through the fuses without risk of ignition.

Electrical Treatment of Sewage.—At the annual meeting of the Association of Municipal and Sanitary Engineers, held at the Institution of Civil Engineers, Westminster, last Friday, Mr. William Webster, F.C.S., read a paper describing the decomposition and purification of sewage by means of electricity. He passed a strong current of electricity through sewage before the meeting, and the solid matter speedily rose to the surface, leaving the fluid apparently bright. He also exhibited a sample of effluent water eight months old, and a specimen of a disinfecting fluid obtained from sewage 12 months ago. The chief expense, he stated, was the engine power, and the process, could be applied to any existing tanks. The thanks of the association were voted to Mr. Webster for bringing before it so important a matter before he had made known his process in any other way. Several speakers considered the process likely to be productive of great results, provided it could be economically applied to the treatment of large quantities of sewage, as the analyses submitted showed the effluent water to be absolutely free from suspended matter.

Provisional Orders.—The Board of Trade report for the past year upon their proceedings under the Electric Lighting Act has been issued, according to which the only application for a provisional order since the last report was that of the South Metropolitan Electric Supply Company, for permission to occupy the City and a select district of the West End of London. After hearing the objections of several of the local authorities named in the application, the Board of Trade granted an order restricted to the parishes of St. James, Westminster, and St. Martin-in-the-Fields, with Waterloo Bridge and a small portion of the Victoria Embankment. It may be remarked here that a Bill to confirm the order was introduced into the House of Lords, and read a first time last week; the standing orders having been suspended for this purpose. Five applications for licenses are recorded, of which only one, relating to Liverpool, has been granted besides the license to the Kensington Court Electric Lighting Company, which was mentioned in the last report. It is probable that the next report of the Board of Trade upon this subject will contain more matter.

Bath.—In a letter accompanying Mr. Massingham's tender for the lighting of Bath, he states that the tender is based upon an estimate to pay only 5 per cent. per annum upon the capital employed, provided everything is conducted upon the most economical scale. He believes it is the lowest tender that has ever been made for public electric lighting, and if accepted a local company can at once be formed for supplying the light permanently for private as well as public use, so that the bathing establishments and other places can at any time be lighted. The seventy-one arc lamps provided for being placed principally at the junction of streets will displace 315 gas lamps, which, reckoned at £3. 0s. 8d. each, make £955. 10s. They also displace eighteen large lamps, twelve of which, considered as costing £10. 3s. 1d. each, make £171. 16s. 6d., a total of £1,127. 6s. 6d. The total cost of the seventy-one arc lamps, reckoning them at £18. 17s. 6d. each, is £1,330. 2s. 6d. This is a lower price than the council was led to expect, the sum first named being 50 per cent. more than gas, whereas the estimate is only 20 per cent. more, though giving several hundred per cent. more light.

Sprague System at Wilmington.—The President of the Wilmington City (Delaware) Railway Company says, concerning the overhead (Sprague) electrical system in use on the Riverview extension: "The system has been in operation here for three months, and from a practical experience during that time we can pronounce it a complete success. In comparison with horse-power we find it decidedly cheaper and more efficient in every way. It is popular with our patrons on account of its cleanliness, its smooth and rapid motion, and especially for the absence of the usually overtasked and labouring horse. Our road is quite hilly, and the cars, loaded sometimes with seventy passengers, climb with ease, at the rate of five miles an hour, a 5½ per cent. grade having a 90ft. curve. The cars are 16ft. long, and each has been running continuously from the start 16 hours a day, making 64 miles daily on the 1 1-3 miles of our extension. At first many persons here were sceptical about the successful use of electricity as a motive power instead of horses, but the practical demonstration made on our line has converted them, and directors, press, and public have only words of praise for electricity, and endorse it as the future motive power for street car traffic."

Bristol Cathedral Lighting.—The following testimonial has been received by Mr. H. G. Massingham with respect to the recent lighting of the Bristol Cathedral, the first in the world to be lighted throughout with electric arc lamps. Messrs. Newall and Co., who have had great experience in electrical work, more especially ship lighting, were first asked to undertake it, but declined the responsibility of what they regarded as an experiment. Mr. Massingham was at their suggestion, communicated with, and agreed to take all responsibility for the electrical portion, Messrs. Newall and Co. supplying the engineering plant used. The lighting proved an unqualified success. The thanks of the committee were embodied in the following letter: "At a committee meeting, held at Mr. Risely's a few day since, it was unanimously resolved: 'That the best thanks of this committee be tendered to Messrs. Massingham, electrician, and Newall, engineer, for the highly successful and intelligent manner in which the electrical lighting of the cathedral was carried out on the occasion of the above services, for their generous aid when contracting for the same, and for the courteous way in which all the wishes of the committee received attention.' Need we say that we are afforded much pleasure in sending the above, and, at the same time, would send our personal thanks for your readiness to meet us in every way. (Signed) H. Swayne, Herbert Riseley."

The Mauritius.—Sir E. Watkin, a few days ago in the House of Commons, asked the Under-Secretary for the Colonies whether the island of Mauritius, which had a naval dockyard, and the fortified harbour of St. Louis was, like Bermuda, unconnected by submarine telegraphic cable independent of foreign interference, with any other portion of the empire; whether the Malagassy Government so long as three months ago expressed their readiness to assist in establishing direct communication through their territory with Great Britain by means of a cable from Mozambique, to be landed at Mojunga, and by the erection of a land line thence to the capital, and onwards to the east coast at Andevoranto, or Vatomandry, with the right to connect the same by cable to Mauritius, and whether he had come to any decision in the matter?—Sir J. Gorst, for Baron H. de Worms, in reply, said there is no direct communication with Mauritius, but messages are sent as opportunity offers by steam vessels from Aden, Natal and Australia. The particular proposal referred to has not come under the consideration of Her Majesty's Govern-

Digitized by Google

ment, but various schemes for laying a cable to Mauritius *viâ* Madagascar have been and still are under consideration. It has not, however, been found possible to make provision for this service, and until arrangements can be made for meeting the cost of a cable, it is not possible to come to a decision as to the particular route.

Laboratory Testing Stand.—A simple and cheap stand for holding laboratory testing apparatus, one that can be modified in any desired direction, is a great desideratum both for private experimental use and for technical classes. Such a piece of apparatus, largely in use in Germany, but little known in England, is described in *The Engineer* for June 22, the device of Dr. Edelmann, who is the author of several works on new apparatus published in Stuttgart. The apparatus consists of some forty parts, which can be mounted in various combinations upon a tripod stand. It includes, among other appliances, two cylinders of vulcanite for electrical insulation purposes, several thin brass rods tapped at each end, five cross carriers, three cross carriers with narrower boring, two hooks with clamps, clamping screws for electrical connections, clamps for holding paper or other thick films, clamps for holding thin films, four nickel-plated balls for use as electrodes, a disc and two points, pincers, insulated handles, a carrier for vacuum tubes, a delicate screw regulator, and so on. The combination of the stand can be used in all manner of complicated laboratory tests, and the borings are made so as to fit the gauges of rods—whether glass, vulcanite, brass or iron—most commonly in the market. The apparatus is in no way protected by patent, Dr. Edelmann wishing it to be considered the common property of men of science. The apparatus has been imported by Mr. Heinrich Trinks, of Primrose Hill.

Creosoted Underground Mains.—The treatment of timber with dead oil of coal tar, commonly termed "creosoting," was introduced in 1838; and timber treated at that time is as sound to-day as then. This method of laying wood underground has been often advocated and has been very largely employed in America for electric conductors. The Eppinger and Russell creosoting works have supplied large amounts to the telephone companies in Brooklyn, Boston, Chicago, and other towns, and to the Edison Electric Light Company of New York, Boston, Columbus, and other towns. The system used by them is termed the Macdonald conduit, and is made in 16-ft. lengths of creosoted timber, cut in sections with a series of semi-circular grooves top and bottom, so that sets of wires can be laid therein. When properly laid it is perfectly watertight and makes a solid block; it can be altered, increased as desired, or wires can be taken out with ease. It is cheap, and easy to lay, and is very durable. The method for laying underground wires in creosoted wood is greatly extending in Philadelphia. Mr. Wyckoff has recently built creosoting works in connection with his wooden pipe factory, and has obtained a contract from the Bell Telephone Company, of Philadelphia, to furnish them his wooden casing for underground wires; they will put several pipes in the same trench from 12 to 70, and it will take millions of feet for the city of Philadelphia. Mr. Wyckoff is also furnishing casing for the subways of New York City, all of which will be creosoted.

Tenders for Lighting Bath.—The report of the Electric Lighting Committee has been issued, giving particulars of the seven tenders received in answer to the advertisement for the lighting by electricity of the streets in the district approved by the Council. The report states: "All the persons tendering concur in recommending the adoption of overhead in preference to underground wires, as being much less expensive, and less liable to failure on account of defective insulation. There are three methods of fixing overhead wires: (1) on poles placed on house roofs, (2) on brackets placed on house fronts, (3) on lamp posts in a line with the kerbstone placed from 100 to 150 feet apart. The last-mentioned is the method recommended." The following are the chief particulars of the different tenders: Mr. H. G. Massingham, Thomson-Houston system, 70 lamps of 1,200 c.p. each, price per lamp on three year's contract, overhead wires £19. 17s. 6d., underground £25. 17s. 6d.; Anglo-American Brush Electric Corporation, 67 lamps of 2,000 c.p., J. Ravennes, London, Brush system, 40 lamps of 1,250 c.p, overhead £26, underground £30; Messrs. C. Allen and Son, Taunton, Brockie-Pell or Pilsen-Joel system, 66 lamps, 1,000 c.p., overhead £21, underground £25, or same firm Thomson-Houston system, 66 lamps, 1,200 c.p., overhead £25, underground £29. 10s.; Messrs. Nicholson and Jennings, London, Brush system, 43 lamps, 2,000 c.p. (overhead only), £30. 8s. 4d.; Messrs. Newall and Co., Bristol, Brush system, 68 lamps, 2,000 c.p. (overhead), £27, underground £31, or Thomson-Houston system, 68 lamps, 1,200 c.p., overhead £25, underground £29; Messrs. Laing, Wharton and Down, London, Thomson-Houston system, 75 lamps, 1,200 c.p., overhead £24, underground £28. The committee have fully discussed the several tenders, and they are of opinion that the one sent in by Mr. Massingham presents great advantages, and that the small extension of the area to be lighted with electric light which it suggests (a plan of which can be seen at the town clerk's office) is well worthy the consideration of the Council.

The "Sun" Miners' Electric Lamp. — Among the electric miners' safety lamps exhibited on the occasion of the reading of Sir Frederick Abel's paper on mine accidents in November, 1877, before the Institution of Civil Engineers, was the "Sun" lamp, which met with commendation from Sir Frederick Abel. This lamp was described shortly afterwards, at which time it had been tested by Mr. C. E. Rhodes, who pronounced it to be fully entitled to rank as a miners' "safety" lamp. He, however, suggested some detail improvements which promised to increase the working utility of the lamp, and these improvements have since been introduced into it, and it has now been successfully tested in practical use in two collieries. In the battery of this lamp the positive element is zinc, the negative element being a plate of special metallic alloy. The weight of each negative element is 6oz., and that of each positive element 3oz., the total weight of the elements being 1lb. 2oz., and the total weight of the lamp 4lb. 6oz. The elements are suspended in a depolarising solution of dilute sulphuric acid, and there is no waste going on while the lamp is not running, although the elements remain suspended in the solution. The battery can be used as a primary, but is at its best as a secondary battery, charged from a dynamo in the usual way. The light is emitted from a glow-lamp of 1½ c.p. nominal, the lamp being protected by a toughened glass cover, and should this be broken the light is instantly extinguished automatically, whether or not the glass of the glow-lamp itself be broken, thus giving absolute safety against risk of explosion. The battery is encased in wood and metal, and the lamp is 8in. high by 4in. diameter. The average electromotive force during a period of ten

Digitized by Google

hours is 3·8 volts, the current through the lamp varying from 0·6 to 0·25 ampere, according to the lamp used. The ordinary run of the lamp is ten hours, but Mr. I. Knowles, of the Pearson and Knowles Coal and Iron Company, having used it in his collieries, reports that it will run for twelve hours, and he states that he considers it suitable in every respect. The New Portable Electric Lamp and Power Syndicate Company, of 43, Coleman-street, London, have also received a highly satisfactory report from the Wigan Coal and Iron Company, who have also used it in their collieries.

Electric Lighting of Tram-Cars in Bradford.—The lighting of tramcars and omnibuses by primary batteries seems to be a favourite occupation of inventors. There is nothing impossible about the idea, the main item being simply and solely the question of expense. We remember to have seen several omnibuses lighted (with a great *eclat*) by "Eclipse" batteries. Nothing more seems to have come of the experiment. This week we notice in the Bradford papers enthusiastic reports of a new (?) invention by M. Charles Gauzentes, a Belgian electrical engineer, which is being tried by the Bradford Tramways and Omnibus Company. The account has this, in common with all primary battery reports, that big claims are made, and no details of cost are given. "The system is the first that has been successfully applied to the lighting of tramcars, and it is the only one of its class in the market. The idea of lighting by batteries is not new; but it has hitherto been unsuccessful in application, by reason of the cost and the unsatisfactory method of manufacture and the fitting of the apparatus. The whole system of lighting," the report goes on to say, "has been carefully revised by M. Gauzentes, and so adapted by him to the illumination of cars that it is practically a new invention." The only details of this new invention given are that it is placed under the seat, that it consists of 12 cells, is charged with a "special liquor," and runs an eight-candle lamp. Now, there is nothing new in all this; we have had patent primary batteries with 12 cells, and eight-c.p. lamps, and special liquors, by the score, worked by enthusiastic inventors, which have always eventually come to grief over the item of cost, and never a one has been made to pay. Far be it from us to discourage any attempt to light 'buses and cars by primary batteries if anyone can prove its economy, or will contract to run it themselves; but we fear the taking advantage of unsuspecting and credulous investors who see an 8 c.p. lamp run with a battery, and who do not realise that electricity by means even of a dynamo and steam-engine (the most economical method) is not yet as cheap as gas or oil, and with zinc—which is some twenty times the price of coal—except as a fad or an experiment, is totally out of the question as regards cost. The experiment continues for three weeks. If the inventor has anything to justify him in raising the hopes of the tramcar directors, or is intending to ask for money, we hope he will give full particulars where there is a fair chance of discussing them, before inducing expenditure which may probably go the way of the score or so of previous primary battery investments.

Incandescent Street Lighting.—Councillor Crowther Davies has been writing to the *Birmingham Daily Post*, stating that he shall shortly renew his resolution to put an end to the contract for supply of electric light at Leamington. Though personally believing that the company has endeavoured to carry out the contract to the best of their ability, he strongly believes (while disclaiming all interest, direct or indirect, in the gas or other lighting company), that the incandescent light, as a street light, is an "experimental failure." The company has had "more time" granted it, but the borough has not had more light. He maintains, in a further letter, that the application of a test will not help matters, and that the contract which stipulated for a certain notice to terminate the agreement leaves the Council quite at liberty to act in accordance therewith, and to make future arrangements for another and a better light, and Mr. Davies says he is satisfied that he has the ratepayers with him in the course he is pursuing. The trouble at Leamington, even if finally made satisfactory, is unfortunate, falling as it does at the time when many other towns are practically considering the question of their own lighting, but its best effect may be in acting as a deterrent to authorities attempting to do in a small way what should only be done, if done at all, in a manner that will prove sufficient for the purposes intended. Whatever may be said as to the present sufficiency of the light at Leamington, and upon the relative advantages of arc over incandescent lighting for streets and public places, it is certainly far from absolutely true that incandescent lighting for streets is nothing but an experimental failure. We are perfectly aware that for many situations of this kind the arc light has, especially in America, a very great superiority in point of number of applications, but it must be remembered that the incandescent light has certain advantages over arc lamps even for public lighting, and if these advantages are desired and the system is definitely decided on, there is nothing to prevent the incandescent light acting its part with satisfaction under its own condition. It may be remembered that the arc lamps on the Forth Bridge were found to entail too much trouble and attention considering the difficulty of getting to them on the works, and large incandescent lamps were substituted with satisfaction, which required practically no attention until they were burnt out. It is, moreover, true that in America, though arc lighting in the streets is carried on almost universally throughout the country, yet there are not a few towns where the public lighting has been carried on successfully for some years with incandescent lamps. One of the most noticeable of these is that of the town of St. Louis, where a plant supplied by the Heisler Electric Light Company has been running for two years, consisting of 1,000 30-c.p. incandescent lamps in a 30-mile circuit. The lamps are run in series on a single No. 7 American gauge wire, and it is stated that seven 30-candle lamps are obtained to the horse-power. Automatic regulation of the power of the lamps is obtained, and transformers or other contrivances are not required. At Vincennes, Indiana, 150 30-candle lamps on a 15-mile circuit are used for street lighting. Other towns have 20, 150, 400 and 1,000 lamps respectively. The Thomson-Houston Company are also installing 32 and 64 c.p. incandescent lamps for street lighting in some cases, on a series circuit, on a method to which we have already referred in our issue of June 29, p. 604, by which the utmost simplicity is attained in incandescent street lighting. It is therefore clear, that authorities, or public companies, having before them the various benefits or defects of the two methods of lighting, and definitely deciding upon the adoption of the mellower and less powerful, but perhaps steadier, less troublesome, and cheaper form of lighting, can rely upon having a satisfactory supply by taking the proper means to obtain it.

NOTES ON DYNAMO CONSTRUCTION.

BY SYDNEY F. WALKER.

(Continued from page 37.)

The difference between the resistance of the air space and that of wrought and cast iron respectively, Mr. Kapp represents by the figures 1440 : 2 and 3. This will give us an idea of the great importance of reducing the resistance of the air space. Take an example : suppose that we have a bobbin whose core is 8in. long and 7in. in diameter ; take first the distance between the core and the pole-piece as $\frac{1}{4}$in., then find the resistance of the air space by Mr. Kapp's formula.

$$\frac{1440 \times 2 \times \frac{1}{4}}{8 \times \frac{3}{7} \times \frac{22}{7} \times 7} = 9{\cdot}6.$$

The denominator representing the sectional area of the air space. Take the distance between pole-piece and core as $\frac{3}{4}$in., as in some of the older types of machines, the equation becomes

$$\frac{1440 \times \frac{3}{4}}{75} = 28{\cdot}8.$$

Now, take the first case, but with bobbin twice the length. We have, assuming the air space to be the same depth, $\frac{720}{150} = 4{\cdot}8$. What does this mean? It means that if, say, we require 100 lines of force in our armature, we shall require 2,880 ampere turns 960 and 480 respectively to overcome the resistance of the air space alone, assuming the formula to be accurate, or we have a clear gain of 1,920 ampere turns by simply reducing the layers of wire on the core so as to bring the latter closer to the poles, and we gain 50 per cent. in either case on the exciting power required for this part of the resistance by doubling the length of the bobbin. This, however, is on the assumption that on doubling the length of the bobbin we are still able to maintain the same clearance between it and the pole-pieces as with the short bobbin, and to provide the exciting power required—that is to say, that we do not reduce the winding space below that required for the reduced number of ampere-turns. If, with the long bobbin, we have to provide double the clearance of the short, we have $\frac{1,440 \times 2 \times \frac{1}{2}}{150} = 9{\cdot}6$ again, and with a long bobbin it is necessary either to allow more clearance, or to increase the strength of the spindle very considerably, the latter being an expensive part of the machine, as in turning it has far more leverage in the centre to pull the spindle out of line, or cause it to spring, than the short bobbin. The next important resistance is that of the armature core itself. It is evident that this will be less, the longer the bobbin is, and the greater its radial depth, as these two go to make up its cross section, and, on the other hand, it will be less, the smaller the diameter. The scope for the latter, however, is limited by the necessity of providing for the wires inside, and for driving, if of the Gramme type ; so that there is another gain from having fewer layers of wire, as less space is occupied inside the core, and therefore the radial depth of the latter may be greater. It will be obvious, however, that it is quite possible to have a short core whose resistance shall be even less than that of a long core. If our core 8in. long and 7in. diameter have a depth of 2in., while our core 16in. long has a depth of only 1in., the resistance of the two are equal ; and if it should be necessary or expedient from other causes to make our long core, say, 9in. in diameter, while our short one remains at 7in., and we have 1in. radial depth in the one case and 2in. in the other, then the resistance of the short core will be less than that of the long core. And this may very easily be, bearing in mind the commercial conditions to which we have to conform, the elements of friction and centrifugal force, and that of magnetic leakage, which will be considered later.

Now, consider the matter of the electro-magnets. A long bobbin almost necessitates long flat magnets, and the spindle at right angles to them, unless either the commutator be placed outside the machine, or be specially constructed. The electro-magnets may, however, be made longer, so as to accommodate the commutator on the old plan, without increasing the magnetic resistance, if they are also made of larger cross-section, and their yokes the same. There is no difficulty in doing this, and it is the plan adopted by manufacturers who prefer to keep to the old Gramme type. The reasons for doing so are principally fitting-shop reasons. It is easier and cheaper to construct the old Gramme type than those in which the bobbin is at right angles to the field-magnets. You can get a round bar of almost any size direct from the works, requiring only to be trued in the lathe, and have its ends turned and fitted, for connection to the sides. Your sides also and pole-pieces, for use with the round bar, if your patterns are carefully made and castings well done, do not require any special tools or much machinery of any kind. With the flat bars used with long bobbins a good deal of machinery is usually required. They must be planed true and fitted to their bed-plates, and then bored for the armature. You have the advantage in this case that you have no joint between your field-magnet, core, and pole-piece, the latter forming part of the former, but it is very doubtful whether in practice there is really an appreciable loss from this cause if the fitting be good. One great gain that it has, however, is in the fact that the pole-piece is of wrought iron instead of cast, though here, also, it is not difficult or expensive to make up the difference by adding to the mass and weight of the pole-piece. The magnetic resistance of the Siemens core is of course less for any dimensions than that of any other form, and it is also easier to drive, as the spindle and core become one solid mass. The objection to this form, however, is in the winding, which will be dealt with later. The magnetic resistance of the disc core is usually high, the cross-section being about the same as that of other machines, but the length, the half circumference of the disc, being larger.

There is a further source of loss—namely, that of magnetic leakage. It must be remembered that the lines of force emanating from a wire are circles, and that in the ordinary wrapping of a magnet, while they enter the iron core on one side, on the other they are open to space, and will form magnetic circuits of their own if the conditions are favourable. If anyone explores the neighbourhood of any dynamo at work, he will always find traces of evident magnetism all round it. Taking the two legs of the field-magnets of a dynamo, the lines of force emanating from the wire on the inner side of one leg will be of the opposite sign to those emanating from the wire on the inner side of the opposite leg, and they will therefore tend to form closed magnetic circuits of their own. These leakage magnetic circuits will obey the same laws as the ordinary circuits—viz., their resistance will vary directly as the distance between the wires, and inversely as the cross section. Here, then, we have an argument, and a very strong one, against the long bobbin, especially if it has a small diameter. Take our bobbin 7in. diameter. Of this, at least 3in. would probably be absorbed in the boring of the pole-piece, and a a further 2in. or more in the winding, leaving only 2in. space from wire to wire. You would have, therefore, for the resistance of this leakage circuit,

$$\text{R.L.} = \frac{1,440 \times 2}{\text{Sectional area}}.$$

Take this at 9in. × 16in., which is by no means out of the way, and bearing in mind that you have two such circuits, and you get

$$\frac{1,440 \times 2}{144 \times 2} = 10.$$

As, however, only half the wire can by any possibility come into play here, this is equivalent to doubling the magnetic resistance of this leakage, but still leaving it a serious matter, as it will be remembered that this leakage magnetism, although it is doing no work, has to be furnished by the magnetising current, and primarily by the engine, so that the efficiency of the machine is thereby reduced.

The other losses that have to be provided for are the energy expended in the wires on the armature and the so-called Foucault currents that are formed in the core itself. Both of these will be dealt with when the construction of the armature itself is considered.

What shall the field-magnets be of—single or double horse-

Digitized by Google

shoe form, or shall they be of multiple form? In the first place the single horseshoe form effect a saving in the amount of copper wire required to do certain work, say, to create a certain number of lines of force in a given armature core. In order that two machines of different types may have the same number of lines of force passing into their armatures with the same exciting power, the resistance of their magnetic circuits must be equal. Assuming that the form and dimensions of the armatures are the same in each case, this can only be accomplished where the machines have one double and the other a single horse-shoe magnet, by making the sectional area of the core of the field-magnet of the single horse-shoe double that of the two horse-shoes; but doubling the sectional area does not double the circumference upon which the wire is wound, or its lineal surface, if flat, and as, in order to create a certain number of lines, what is required is a given number of ampere turns, irrespective of the extent of surface of the field-magnets, the single horse-shoe magnet will thereby have the advantage. To give a numerical example—say we have a dynamo of the double horse-shoe type, whose field-magnets are bars 5in. in diameter, and we wish to construct a single horse-shoe dynamo to do the same work, we require first to find the sectional area of the 5in. bar, which is 19·6 square inches. Our single magnet-bar must therefore have an area of 39·2 square inches, which corresponds to a diameter of about 7·1in., and the circumferences of the two circles are 15·7in. and 22·3in. respectively. That of the single magnet, not being double the circumference of the double one, but only about 50 per cent. more, so that in place of having to use double the amount of copper on the single horse-shoe you have to use about 50 per cent. more; or you affect a saving of 25 per cent. This, of course, is not strictly accurate, as the outer layers will be larger in proportion in the case of the single than the double magnet. With a flat bar, it is even more strikingly illustrated. Take a bar, say, 12in. × 2in. = 24 square inches sectional area. The length of wire required to pass once round it is 2 (12 + 2) = 28in. Now, double the sectional area, which can be done by doubling the thickness, or making it 12in. × 4in. = 48 square inches. The length of wire required to pass once round it is now 32in., or the increase is only as 28 is to 32—say, $\frac{1}{7}$th. The magnetic leakage is also a serious matter in the construction of the single horse-shoe dynamo. In many of these the magnets are above the armature, and they stand upon an iron bed-plate, magnetically separated from it by a sheet of zinc. Applying the reasoning that has been used in the case of the long flat magnets, it will at once be seen how serious the matter is, as the magnetic resistance of this leakage circuit is made up of that of the massive bed plate and the thin zinc plate. Where the bobbin is over the magnets of course this does not apply.

Then as to multipolar machines. As there are in these machines four, eight, or more paths for the magnetic current, if we may so term it, each of these paths may have four or eight times the magnetic resistance of the single horse-shoe magnet. In other words, in the multipolar machine, other things being the same, the iron cores of the field-magnets may have a sectional area $\frac{1}{4}$ or $\frac{1}{8}$ that of the single horse-shoe magnet; but if the exciting power is to be the same, it will entail the expenditure of a greater amount of copper wire. There are, however, two sides to the question in this case. Taking the case of our double horse-shoe magnet, with 5in. bars, and making it a four-pole machine, we can now have our bars each about 3·6in. diameter; and if we make it an eight-pole machine, we can have them about 2·3in. diameter. Now, there is practically no difference in machining a 2½in. bar and a 4in. bar, while the areas of these are respectively about 5in. and 12½in., so that by using a 4in. bar instead of a 2½in. we can reduce the magnetic resistance by a very appreciable amount, and thereby reduce the number of ampere turns and the wire required without increased cost for machining, while retaining the advantage of the double or quadruple induction. With the single horseshoe, however, the increase of an inch to the diameter will materially increase the weight and cost of machining, while the sectional area of the bar would then not equal the combined area of those of the eight-pole dynamo. There is another feature, however, to be considered in connection with multipolar dynamos. The four-pole machine has to furnish two distinct paths for the lines of force, and the eight-pole dynamo four such paths, where the single and double horse-shoe dynamos only require one path; but as the two paths and the four paths have only to accommodate a half and a quarter the number of lines that the single path has, the magnetic resistances of each path in the multipolar machine may be double or quadruple that of the single path in the others for the equivalent exciting power without any loss of efficiency. The meaning of which is, that the work being more divided, a multipolar machine may be constructed lighter than either of the others. There is also a form of multipolar dynamo made by Messrs. Elwell-Parker, Mr. Reckenzaun, and others, in which the magnetic circuit is continuous through the two inductive spaces. It has, of course, twice the resistance, other things being the same, that either of the single circuits on the other plans have.

Then if the single horse-shoe magnet be adopted, how shall it be mounted? There are at present three methods in the market. First, the Edison, where the field-magnets are on top; the legs of the magnet-bars, whether they be two or six, step into iron shoes forming pole-pieces, and these rest on a cast-iron bed plate, which carries the standards for the bearings of the armature spindles. Here we have two grave faults to find. The construction is wrong mechanically, the centre of gravity of the whole machine being too high, notwithstanding the weight of the massive pole-pieces and armature. In Dr. Hopkinson's improvement of Edison's machine, this fault is partly reduced. Further, the item of leakage across the poles may be serious; this has already been dealt with. The second plan of construction using the single horse-shoe magnets is that of Mr. Kapp, which gets over the difficulty mentioned pretty well. Mr. Kapp simply inverts his dynamo, carrying his armature and pole-pieces at the top, the magnet legs being spread out in the the form of an inverted V, so as to give stability to the structure. The standards carrying the bearings form part of the bed plates as usual. The other plan is to have the field-magnets horizontal and the armature either parallel or at right angles to the line of the field-magnets, standards being provided for one or both bearings of the armature spindle. The form of the machine is as though one set of field-magnets were cut off a double horse-shoe machine. In the Jones' dynamo, the field-magnets are horizontal, the spindle running in a long bearing extended from the yoke to the pole-piece, the armature being of the disc pattern and the pole-pieces forming shoes that encircle it on both sides for a large portion of its circumference. The long bearing is unnecessary, but it gives increased steadiness, and does away with the necessity for a second bearing at the other end.

Next, what form shall the armature take? It will have been decided by this whether it is to be long or short. Shall it be of drum pattern or ring pattern? or again on the disc or Pacinotti pattern? Shall its core be of wire, discs, ribbon, &c.? Shall it be light or heavy? There are two distinct lines that a maker can go on to begin with. He may make his bobbin very light and run it at a high speed, or he can make it heavy and run it at a low speed. From the important bearing that speed has upon the output of a machine, a maker would probably be wise, except in special cases, to make his armature light and run at a moderately high speed. As the loss by friction will depend upon the weight and speed, if you double the weight or the speed you double the frictional charge, the other factors being constant. The question of repairs and renewal comes in here. The armature is the part that has to bear most of these, so that the smaller and cheaper this can be made the better. The writer is aware that Mr. Kapp has committed himself very strongly to low speeds; but, while fully appreciating the advantage of running a heavy armature at a low speed, he sees no necessity for running a light one slowly, and he believes that you are wasting power and material by doing so. Where it is a necessity of the case that the armature shall be coupled to the engine, and you

Digitized by Google

are unable to make the latter run more than, say, 300 to 400 revolutions a minute, you must work to these conditions, and as you must make up the loss somewhere, you may as well do so by having a large heavy bobbin, as in any other way, provided that you fulfil the other necessary conditions. There is one very simple method of reducing your speed, of course—viz., by increasing the diameter of the bobbin. The number of turns (N P) will vary as the diameter of your bobbin, and so with a bobbin of twice the diameter you can run at half-speed with the same result; but you cannot increase the diameter of your bobbin without increasing the dimensions of your dynamo as a whole—so that if you construct slow-speed dynamos on these lines you must make special patterns for them; and with a large-diameter bobbin you must have more iron in your core, otherwise your magnetic resistance will rise and reduce the efficiency of the machine once more. So that, after all, a slow-speed machine is merely a larger and more expensive machine for the same work. In other words, running a dynamo at a low speed is only one way of running it under power, and, in the writer's opinion, by no means the best way.

(To be continued.)

ROYAL AGRICULTURAL SOCIETY'S SHOW AT NOTTINGHAM.

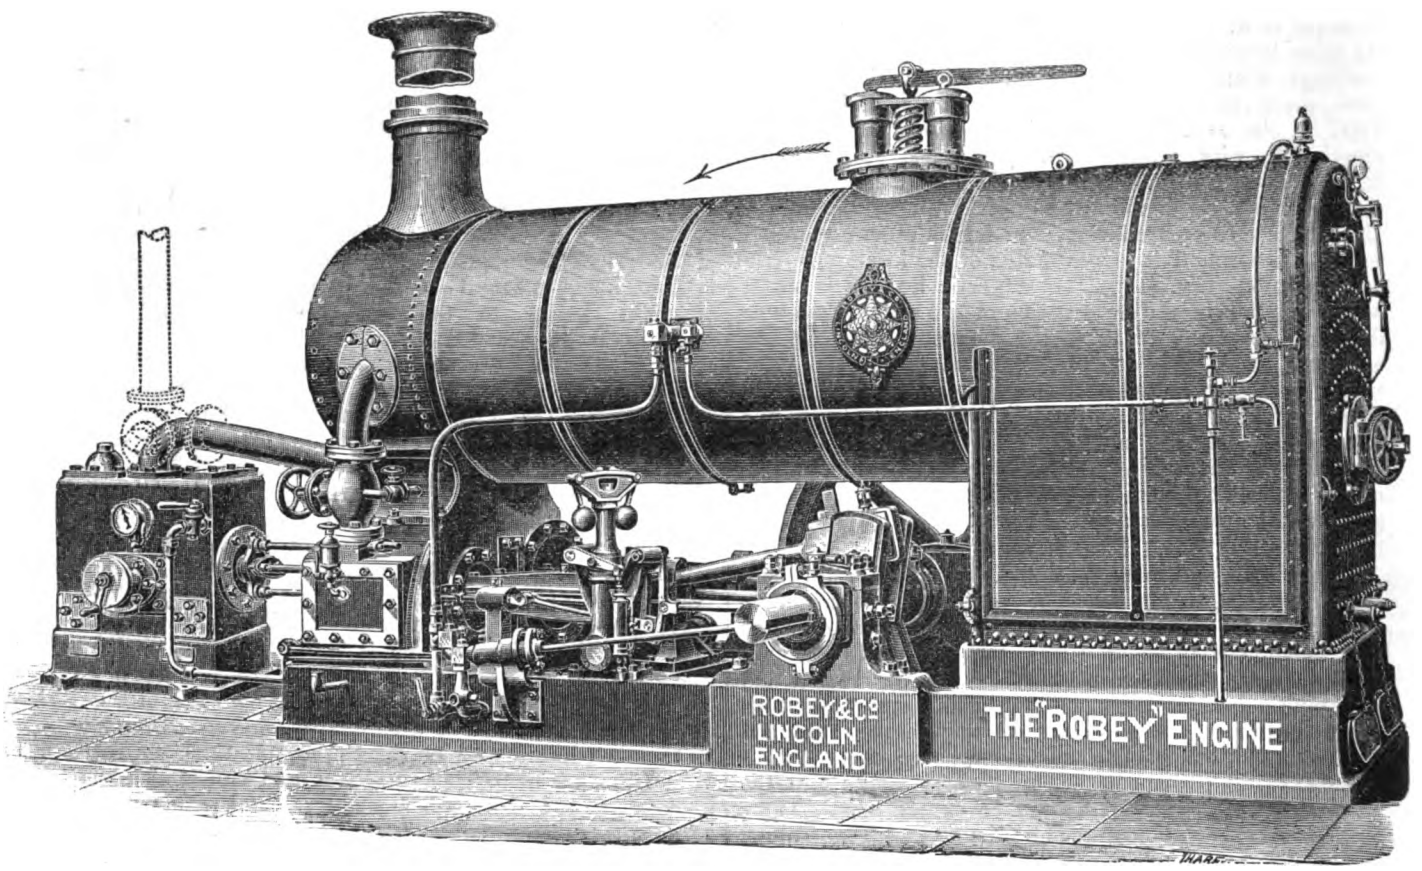
In our last issue we referred to engines of the undertype class exhibited by Messrs. FOWLER and Co., and Messrs. RUSTON and PROCTOR, and we now give an illustration of a similar engine by Messrs. ROBEY and Co., of Lincoln. The engine exhibited was a semi-fixed compound engine of 12 h.p. nominal, similar to the engines usually built for electric light installation and for driving machinery where steady running is a *sine qua non*. The working parts are perfectly balanced, so as to run safely at high speed. If we mistake not, this was the type of engine used at the Newcastle Exhibition last year, and which we saw running under various circumstances, but always satisfactorily. The boilers of these engines are made to work with 150lb. steam pressure, and are made wholly of Siemens-Martin steel. The governing of these engines, like the other cases we mention, has had special attention; indeed, Mr. Richardson is an expert upon this question, and it is to him we owe the electric governor, which can be applied to any of these engines, though usually, we believe, they are fitted with the Proëll gear. It was only in our issue of March 2 that we previously referred to this class of engine and discussed diagrams taken from one.

Messrs. ROBEY and Co. also exhibited a stationary engine for mill work, with "trip" valve gear. As it is our intention to consider specially the question of the governing of engines for electric light work, we shall defer our remarks upon this gear.

Messrs. DAVEY, PAXMAN and Co., of Colchester, at their stand exhibited only specimens of their Essex boilers; but they had working at the dairy a portable engine similar to the one which gained the society's prize last year. We have not previously illustrated the Essex boiler, which for many purposes will be found a convenient steam generator. It is a vertical boiler, and is made from 2 h.p. upwards.

From the illustration given it will be seen that a curved neck secured to the top of fire-box conveys the products of combustion into a chamber to the left, where they are burnt. This chamber is of a triangular shape in plan and has an outer flange by which it is riveted to the shell of the boiler, and a door is fitted. An exactly similar chamber is in like manner secured at the right side, and is fitted with a door and uptake, and constitutes a smoke-box. These two chambers have a number of tubes of a somewhat semi-circular shape uniting them, the curve being of a greater radius than that of the boiler, suiting it in such a way that the tubes can be easily put in or withdrawn without removing either tube chamber. The chambers are formed while hot in a special hydraulic pressing machine, and are then annealed, so that all the best qualities of the steel are preserved. The shape of the flues causes a centrifugal action in the hot gases which brings every portion of them into direct contact with the metal of the tube, so that the highest efficiency is secured from the heating surface, while at the same time full circulation of the water is secured without those violent currents which are a defective feature of other forms of vertical boiler, and which produce priming and very wet steam.

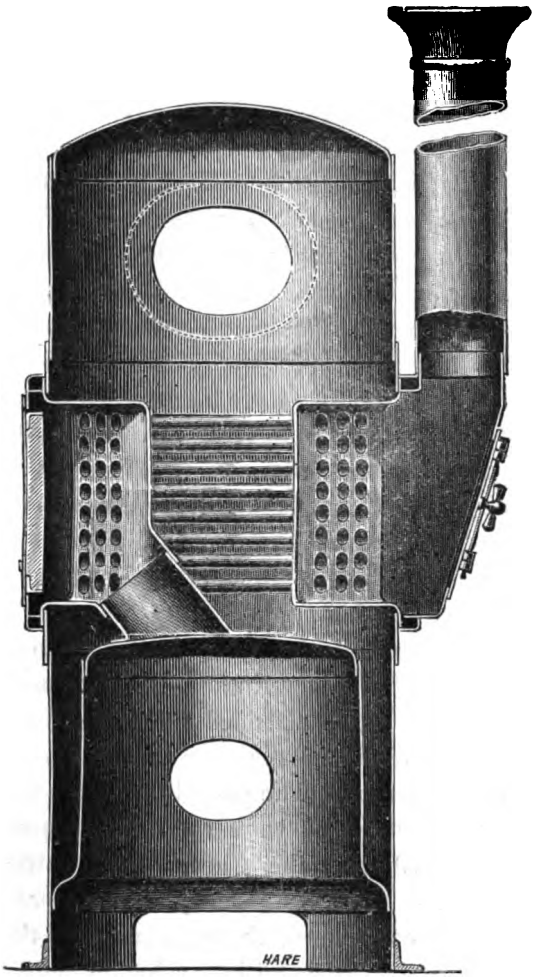
The combustion and smoke-box chambers are made of the very best mild steel, pressed out, including the flange, in



Messrs. Robey and Co.'s 12-h.p. Undertype Engine.

Digitized by Google

one piece. This is one of the best pieces of stamping work we have ever seen. It has been so carefully and thoroughly worked out that no reduction of area takes place, and it is of uniform thickness throughout. A little consideration will show that Messrs. Davey, Paxman, and Co. have ingeniously contrived to attain in a great measure that breaking up and "eddying" of the heated currents, causing them to impinge more directly upon the heating surface parts, which is necessary to secure the largest possible portion of the heat for the generation of steam. As will be seen, there is no part of this arrangement difficult of access, expensive to make, or liable to get out of repair.



Messrs. Davey, Paxman and Co.'s Essex Boiler.

The boiler now under notice is not only a good steam generator in which a large amount of efficient heating surface can be got into a little room, but it is essentially a strong, well-designed, and serviceable boiler. Davey, Paxman, and Co. exhibited on their stand sections of the boiler, showing how simple is its construction.

THE ANGLO-AMERICAN BRUSH COMPANY.

The following circular has been sent to the shareholders of the Anglo-American Brush Electric Light Corporation, Limited:—

The directors have reason to congratulate the shareholders upon the result of the litigation with the Edison-Swan United Electric Light Co., Limited, and take this opportunity of putting before them the facts connected with this important case.

It is doubtless within the knowledge of many of the shareholders that the Edison-Swan Co. about a year and a half since obtained a judgment in their favour against the manufacturing firm of Woodhouse and Rawson upon two patents held by them—viz., that which was considered as the fundamental Edison patent for the general principles involved in the manufacture of incandescence lamps, No. 4,576 of 1879, and that of Sawyer and Mann (known as the Cheesbrough patent), No 4,874 of 1878, for a process in the manufacture of carbon for electric lamps. These actions were gained by the Edison-Swan Company in the Court of First Instance, before Mr. Justice Butt, and subsequently in the Court of Appeal.

Following these decisions, the Edison-Swan Company commenced a system of intimidation against the users of the Victoria incandescent lamps, rendering it necessary for the corporation to indemnify all purchasers or users against loss or damage, and to call upon the Edison-Swan Company to withdraw such notice, or to take such action as would justify their procedure.

At the same time, not wishing to involve the corporation in the uncertainty of costly litigation in respect of patents which, as has been stated, had been upheld in the Courts, your directors offered to pay such a recognition royalty as should not be injurious either to the trade or to the interest of the public, provided that the Edison-Swan Company on their part would recognise also, by payment of a non-prohibitive royalty, the valuable patents of Mr. Lane Fox, the property of the corporation, which the Edison Company use in their manufacture.

These negotiations, which were initiated and conducted by your directors in the most friendly spirit, and which, from every possible point of view, were honourable and equitable to all concerned, were rejected, and the prolonged and costly litigation which has just been terminated was forced upon your corporation in defence of their rights, and to protect one of the most vital and important branches of their business.

The action was nominally brought by the Edison-Swan Company against Mr. William Holland, of Albert Palace, who was using, and the Jablochkoff Electric Company who had supplied, a large number of the corporation's lamps, and to whom the corporation had given indemnities.

Upon the application of the defendants that the Anglo-American Brush Electric Light Corporation should take part in defending the action, opposition in the courts of law was raised by the Edison Swan Company, thus endeavouring to preclude the corporation from justly protecting their own interests by defending the attack made on their lamps, but an order of the Court was obtained enabling them to defend as third parties.

In consequence of the procedure of the Edison-Swan Company, your directors considered that it was necessary to protect your interests by demanding recognition of the Lane Fox patents held by the corporation, and they therefore commenced an action against the Edison Company for infringement of two of them. This action will come on in due course, and your directors, having acted upon the best technical and legal advice, await the result with every confidence.

After an exceptionally exhaustive trial occupying 22 days, the action resulted on Monday last in a judgment in favour of the corporation upon the main issue—viz., the Edison patent, and in favour of the Edison-Swan Company upon the minor issue of the Cheesbrough patent.

The effect of this judgment is to invalidate the Edison patent, thus destroying the claim of the Edison-Swan Company to a monopoly for the "carbon filament."

The plaintiffs' Cheesbrough patent, with which they claim a special method of preparing the "carbon filament" of incandescent lamps, is upheld, and the corporation (who have always contended that they did not employ the process for the object intended and patented by Sawyer and Mann), were held to infringe this patent. This latter decision, however, in no way affects the corporation's right to manufacture incandescence lamps, and they will continue without interruption to make Victoria lamps under their own patents, which are quite independent of any process which can be considered as falling within the scope now given to the Cheesbrough patent.

With regard to the costs, those incurred in respect of the Edison patent are to be borne by the Edison-Swan Company upon the higher scale, and those incurred in the minor issue of the Cheesbrough patent, which are relatively small, are to be borne by the corporation.

It is quite possible that the Edison-Swan Company may appeal against Mr. Justice Kay's judgment; but your directors have not the slightest uneasiness as to the result.—By order of the Board, E. GARCKE, manager and secretary.

THE
ELECTRICAL ENGINEER.

Published every Friday.
Price Threepence; Post Free, Threepence Halfpenny.
Editorial and Publishing Offices:
139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—

	3 months	6 months.	12 months.
United Kingdom.....	3s. 3d. ...	6s. 6d. ...	13s. 0d.
Within the Postal Union	4s. 4d. ...	8s. 8d. ...	17s. 4d.
Other Places.....	4s. 10d. ...	9s. 8d. ...	19s 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, ESQ., *President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of* W. H. WOLLASTON, M.D., F.R.S., *and on April 20th we gave that of* SIR HUMPHRY DAVY, F.R.S., *whose fame as an electrician is still more prominent than that of* WOLLASTON. *Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of* PROF. D. E. HUGHES, F.R.S.

HONOURS DIVIDED.

If half a success is satisfactory, then the litigants in the matter of incandescent lamps must be congratulated, for each side has defeated one wing of the opposition. There is no doubt, however, that when the first flush of victory and defeat has passed away, neither party will be satisfied with the result, and the case will go forward to appeal. It is unfortunate that it must be so, because the sole gainers in the end will be the lawyers. An absolute monopoly seems to be impossible, and if this fact had been recognised years ago, would-be manufacturers of incandescent lamps would gladly have paid a small royalty, which payment would have been far better for them, and far more beneficial to the holders of the controverted patents than these costly processes at law. Before we explain why it is impossible that the case can remain as it is, let us in the first place put the present position fairly before the reader. We have hesitated to report the mass of evidence that has been given, and we have no cause to regret such hesitation, as the judgment of Mr. Justice Kay is a fair summary of the position. Certain lamps manufactured by the Brush Company were supplied to the Jablochkoff Company, and used at the Albert Palace. The Edison and Swan Company believed the manufacture of these lamps to infringe patents held by them, and thus believing were obviously entitled to test their belief at law. An action was commenced, and has really been defended by the Brush Company, who gave an indemnity to the purchasers and users of the lamps. The patents which it was contended were infringed were the Edison patent No. 4,576 of 1879, and the Cheesbrough patent No. 4,874 of 1878. It is unnecessary for us to enter into much detail concerning these patents, for they are household words with all interested in lamp manufacture. There exists a widespread feeling of discontent among those who fancy a good business can be made by the manufacture and sale of lamps, that hitherto these patents have been upheld. It is but natural when an article is in extensive demand to envy the patentee, and human frailty is apt to try if it cannot in some way or other get round the patent and take a share in the profits. Thus it is that men with money and brains seeing that incandescent lamps would command an increasing sale are hoping to break down the patents, and so be able to commence to manufacture at once. We are wandering, however, into an homily on attempts at money making. The parties mixed up in the case just finished stand in a different position towards each other, that many other parties—Edison, Swan, and Lane Fox—were each and all investigating and patenting about the same time. It is and it must be admitted that they were working more or less independently of each other, and suppose we admit their investigations ran somewhat on the same lines,

Digitized by Google

the sole question becomes one of priority of date and validity of patent. Our readers must read the judgment, as given elsewhere in our pages, with close attention to understand the position we take in the matter. We must confess that even after once or twice reading the judgment we were not prepared for the criticisms urged against it, and for which we are indebted to a legal friend who has had a unique experience in patent law, and especially so far as it is connected with incandescent lamps.

The judgment of Mr. Justice Kay was to invalidate Edison's patent, so that, so far as this part of the case was concerned, the Brush Company were victorious, and, in the second place, to hold that the Cheesbrough patent had been infringed, and thus, so far as this was concerned, to grant an injunction.

We are fully aware that what we are about to say is contrary to the opinions expressed by some of the eminent legal luminaries engaged in the case, but nevertheless the fact will have to be considered, and for the moment we see no reason why on appeal this judgment should not be reversed. If the anxiety of waiting the result of appeal is to be undergone, the sooner the final solution is arrived at the better. Our wish is to see no more litigation, but if it cannot be avoided, to see it over as quickly as possible. Mr. Justice Kay held that Swan's lecture experiments did not anticipate Edison because "*these were experiments which did not succeed in providing a commercially successful result before Edison's patent.*" On coming to the reasons for invalidating Edison's patent Mr. Justice Kay said: "*Secondly, because his specification does not describe a lamp which ever became or, as I think, could have become commercially successful.*"

The contention we have to put forward is that not being *commercially* successful is no reason for the invalidation of a patent. The facts of the case would be these. Edison, or Swan, or Lane-Fox would commence to experiment. For argument sake, let us stick to Edison. He would arrive at certain results, which admittedly show how to make lamps, some of which burn at least 60 hours. These results he would hasten to patent, and so obtain the groundwork of protection for his work. The experiments would not cease, but would result in further improvements. These improvements would be patented and assume the place of satellitic patents round the central luminary patent. The commercial lamp would be manufactured according to the most improved method found out, but surely that fact does not invalidate the original patent. If it does, no patent is valid unless it specifies a perfect machine, or rather the patent specifying the most perfect machine invalidates all patents on the subject taken out before. Mr. Justice Kay's contention is, we believe, diametrically opposed to that of Sir George Jessel in Otto *v.* Linford, wherein it was set forth that of course experiment and improvement follow after experiment, and patent follows after patent; the commercial article being that manufactured according to the latest improvements.

Whether Mr. Justice Kay's judgment will be upheld because of the other reasons given is a matter upon which we offer no opinion, but to make the validity of a patent depend upon whether or no the article has succeeded commercially, as manufactured according to the specification, is a matter that cannot by any possible means be allowed to be recognised till it has been upheld by a higher jurisdiction.

There is much more to be said on this question of patents. Rumours are already rife as to what lamp manufacturers are going to do now they can and will make lamps without infringing the Cheesbrough patent, but we must advise caution. *Mora omnis ingrata est, sed facit sapientiam.* We have strong opinions about monopoly; about the validity and invalidity of certain patents; about the advisability of litigation; but our opinions are not stamped with the impress of the law, and may be incorrect. Consider the position if this case goes to appeal, and the judgment, so far as Edison's patent is concerned, is reversed. Is not Swan's patent the next in importance, and if so, how far do subsequent patents trespass upon and the manufacture infringe this? The Seel Company, Westinghouse Company, and others again contend that their patents are absolutely outside the Edison-Swan combination, and if this is the case, no doubt the latter must depend for immediate success—as under any circumstances they must do in the course of three or four years—upon excellence of manufacture and cheapness as regards selling price.

ELECTRIC LIGHT RULES.

We had hoped that all difficulties with regard to duplicate electric light rules had been overcome, and that we should hear no more of the subject. We are informed, however, that not only is the subject not dropped, but that a fresh attempt is to be made to force another set of rules down our throats. No doubt the electric light engineer is a long-suffering person, but there certainly is an end to his patience and that end has been reached in all that concerns such rules. It may be well to speak plainly to the busybodies who are trying to force these new rules forward. The profession will not have them, nor will the public tolerate them. It is quite enough to be compelled to work in accordance with one set of rules; but if variations playable at the sweet will of any single or any collection of offices in antagonism to the principal offices are to be put forth, the sooner the instrument of torture is stopped the better. There cannot be two different rules about the same thing, and both be right. If, on the other hand, the rules are the same, where is

Digitized by Google

the need of a duplicate set? We have now in existence the Phœnix rules, which have been elaborated after years of experience, and in consultation with the best known electrical engineers, fortified, so to speak by the society's rules, which, as was indicated in the recent discussion, are not intended to be anything more than scientific guides determining the theoretical lines upon which the practical rules must be based. There is no indication that the proposed new rules have been drawn up as the result of experience or after consultation. Their only object can be, in the first place, to sow dissension among the offices, and, in the second place, to exasperate the practical men who will never know from day to day what changes will take place, or what differences will arise between the various sets of rules. It is necessary to be emphatic upon this question, as the late constant agitation is detrimental to increase of business. Great latitude must necessarily be allowed to fire offices in their method of conducting business, but in the question of these rules there is no room for latitude; for saying the same thing in different words does not constitute a different rule, and the multiplicity is exceedingly vexatious to the engineer, who has to interpret the language and find out exactly what the author means. The door is opened for bad materials and workmanship, and this will surely result in loss to the offices. Whichever way the matter be looked at, alternative rules will be found to be a mistake, lead to endless trouble and confusion, and rouse angry feelings amongst those who should be working harmoniously together. It is to be hoped, therefore, that this new attempt to foist more rules will be met with a decided negative.

CORRESPONDENCE.

HOT BEARINGS.

To the Editor of The Electrical Engineer.

Sir,—One cannot but admire Mr. Thackeray's ingenious application of the Bourdon tube in his instrument for the detection of hot bearings, but his arguments do not convince me that there is a demand for such appliances. I think he defeats his own argument, in that whilst speaking of the difficulty of "feeling" the crank-pin of a fast-speed engine he gives as an example "ships being brought up," &c. Query—What ships (excluding such as torpedo boats) use fast-speed engines?—Yours, &c.,

London, W., July 17, 1888. F. Broadbent.

A TRADE ASSOCIATION.

To the Editor of The Electrical Engineer.

Sir,—The subject of forming an association to represent the commercial interests of the electrical industry has been frequently under discussion during the past few years, and there is apparently a concensus of opinion in favour of some kind of organisation being formed to secure united action; but the chief reason why the past attempts to establish such combination have failed is the difficulty of defining the scope and limits of the proposed association.

We all recognise the necessity for combination in matters of common interest; but we are not all agreed as to what our common interests are. This is probably attributable more to the peculiar conditions of the industry in this country than to any fundamental difference of opinion. My object, however, is not to discuss this, but to point out how I think the difficulty referred to can in a large measure be overcome.

The proposition before us now is that we should assist the London Chamber of Commerce to form an Electrical Trades Section. This is not a new idea, for it has often been spoken of, and was suggested by me to the Chamber more than a year ago. There were, however, at that time difficulties in the way of the scheme being carried out, but now that the Electric Lighting Act has been amended, we may expect the industry to enter upon a new phase, and united action will become more important than ever.

We are indebted to the editors of *Electrical Plant* for reviving the suggestion that we should avail ourselves of the organisation of the London Chamber of Commerce, and in view of the public meeting which the Chamber will shortly convene in regard to the matter, the present is an opportune time to point out the advantages which the proposed arrangement offers.

The Chamber consists of firms and individuals, and anyone feeling an interest in the transactions of the Chamber can become a member upon payment of an entrance fee of two guineas and an annual subscription of one guinea. Its work is divided among different trade sections, which are again divided into sub-sections according to the needs of the respective industries.

The sections are composed of representative men, selected from the members, and one member of each section is elected to the General Council. In this way each trade is brought into communication, through its representative, with all the other trades represented by the Chamber, whilst the various trade sections are not precluded from taking independent action in regard to their own esoteric affairs. The status possessed by the Chamber would at once secure to the electrical industry an influence in Parliamentary and official matters which would be practically unattainable by a separate association formed under existing conditions. The Chamber has been established many years, has done much good work for other industries, and its organisation and its mode of procedure are well defined and intelligible, and the secretary of the Chamber has had a large experience in the best methods of promoting and defending trade interests. We should therefore have the enormous advantage of being relieved from the unprofitable work of defining the precise functions of an organisation and of settling its constitution and rules. All that is necessary is that those who are concerned with the commercial interests of the business should allow themselves to be nominated as members of the Chamber, and then elect a representative section or committee. We should not have to concern ourselves with questions of ways and means, for all necessary office accommodation, staff, and a good central place of meeting would be provided for us by the Chamber.

The monthly journal and the annual volume of proceedings published by the Chamber afford means of inter-communication, and of permanently recording the work of the Chamber in regard to our affairs. The facilities of the Chamber for obtaining reports on the state of the industry in other countries, and for collecting statistical information, are such as no separate association that we could form at present could hope to secure. The following extract from a recent annual report of the council will indicate the special advantages offered to individual members: "Although the more immediate object of the Chamber is to serve the interests of members in their collective sense, it is also sought, within the limits of impartiality and fairness to assist individual subscribers, not only by the communication of information as to treaties, tariffs, prices, foreign legal procedure, foreign exhibitions, the registration of trade marks, and the issue of certificates as to local trade customs, but also by the influence of the Chamber being employed to obtain the support of H.M Government to members' interests in foreign countries. It is not too much to say that there is very little information in or out of the office which cannot now be obtained and transmitted with the least possible delay."

It may perhaps be urged as an objection to the proposal that those members of the industry who are resident in the

Digitized by Google

provinces would feel themselves excluded, but the membership of the Chamber is not limited to persons residing in the metropolis, and the inconvencience to which country members are put by the meetings being held in London must necessarily apply to every organisation having its headquarters in London. On the other hand, those members of the industry who join the provincial Chambers of Commerce are brought into communication with the members of the London Chamber by means of the Associated Chambers of Commerce, a central body which represents now some 70 Chambers of Commerce in all parts of the United Kingdom.—Yours, &c., E. GARCKE.

Belvedere-road, S.E., July 16, 1888.

ELECTRICAL ENGINEERS.

I.—MESSRS. R. E. CROMPTON AND CO.

In view of the rapid extension of the electric lighting industry that is now likely to take place in consequence of the passing of the Electric Lighting Amendments Act, we shall take the opportunity of giving a series of articles descriptive of the works and resources of our prominent electrical engineering firms and companies, with special reference to their facilities for complete and extensive dealing with the problems now before the profession in the question of designing, manufacturing, contracting, and carrying out of large installations for central stations for the public supply of electric light.

We are of the opinion that the delay to the extension of electric light in this country, owing to the first deleterious effect of the first Electric Lighting Act, is by no means an unmitigated evil, and that, however, we may, with disappointment, regard the great extension of the light in America and elsewhere, as compared with the very modified application for public use in England, it cannot but be felt that the loss of time which has taken place will be far more than compensated in future by the greater security, and the better and more scientific methods of dealing with the great problems involved, than would have been possible had the work been tackled at the outset with only the knowledge possessed on the early development, before real and solid engineering experience was grafted on to the inventions of the electricians. Municipalities and vestries almost innumerable have been quietly and industriously investigating the question, and more or less fitting themselves for dealing in a practical and complete manner with the introduction of the light in their localities as soon as the present Act should take effect. Sufficient capital for new companies will not be wanting when it is seen that there is a reasonable prospect of good return for the outlay, and there is little doubt that the capabilities of our electrical engineers will soon be taxed to the utmost.

Themselves keenly alive to these possibilities, Messrs. R. E. Crompton and Co., of Mansion House-buildings, E.C., and Arc Works, Chelmsford, have taken time by the forelock, and last week issued invitations to a number of the daily press, together with the technical journals, and arranged a day of inspection of their works with the idea of pointing out the facilities which they now possess for taking in hand contracts on a large scale. The works of Messrs. Crompton and Co., situated in a charming and convenient country locality, easily allowing any desired extension, and at not too great a distance from London, were started at first on a small scale, and have grown with the growth of electrical engineering, and now occupy an extent of six acres in area. The workshops throughout are conveniently laid out, and are kept very clean and neat in all departments, everything seeming to be in order and under first-class management.

POWER AND MACHINING DEPARTMENT.

On the ground floor, we see the long machining-room, with power lathes, planing machines, drilling and shaping machines of latest patterns busily turning out dynamos both of little and of giant size, and all kinds of electrical fittings. The machinery for the whole works is driven by two engines placed in one compartment of this floor, indicating respectively 80 and 30 h.p.; steam for these is supplied from boilers at the back at 140lb. pressure. One of these engines can be driven separately, for testing the new dynamos as they are finished, on a special bed-plate, to which they can be bolted; and as in many cases the present system of dynamo running seems to tend towards direct driving with high-speed engines, a special shafting with bolted flange can be used for testing such dynamos, as if they were run direct, in exactly the manner they are to be used.

FOUNDRY AND FORGE.

To the back of the machine shop is a well-appointed foundry, with appliances for making the copper and other castings necessary for electrical work. Commutator pieces and bearings, parts of heavy switches, contacts, plates, &c., are here in progress. One interesting and time-saving idea is that of casting copper contact screws with the screw threads already in them, by means of a screw core to the pattern-box. The screws thus cast require, of course, but little surface-turning.

A separate building is devoted to iron-forging; smiths' anvils of the ordinary type are supplemented with a steam hammer, with which, by means of various shaped anvils and bosses, the iron parts required in the work can be rapidly turned out. The eyelet screws for lifting the dynamo are forged under the hammer at white heat with practically but two or three blows and deft movements of the forgemen, and need little but filing the edges to render them fit for use. Other parts of machinery are equally able to be dealt with.

WOOD SAW AND PATTERN SHOP.

A large amount of wood is required, both for making up of parts, and for making the various patterns required for the machinery. The circular saw used in cutting the wood is driven by an electric motor, which answers its purpose admirably as a wood-cutter. One of the old type of Crompton machines is run backwards as a motor from current supplied from a central dynamo, and the normally high rate of revolution of an electro-motor is, of course, advantageous in this direction. Its use is as simple as can be desired, a cross-bar moved by the workman moving a switch on or off, and the motor starts at full power almost instantaneously. A further motor is used to drive the shafting and belts for the lathes and drilling machines of the pattern shop, and perform its part with all satisfaction. In this department, which may be called one of the highest of mechanical skilled trades, numerous clever workers were engaged in turning out patterns of the latest required details of the large switch-boards and electric crane machinery now on hand.

TESTING DEPARTMENT.

The testing department is one of the most necessary in an electrical engineering works, and great care has been taken to get all the necessary apparatus in as convenient a shape and arrangement as possible. Wire and cables from the dynamo machines are led under the floor to convenient boxes, to which connection can be made for testing any new dynamo. Resistances are ranged in large coils outside in the archway, where they can be kept cool, and an arrangement of wire gauze resistance is also fixed up, where, on occasion, as much as 150 h.p. can be absorbed. For additional work, a water resistance, with lead conductors, in a tank which can be filled with water, is also kept handy. A large switch-board on the back wall inside allows of any arrangement of connections. A dark room, furnished with a D'Arsonval reflecting galvanometer, Wheatstone bridge, and other measuring apparatus for testing the resistance of the armatures, &c., is also provided. In the office is also a very delicate apparatus, with standard cells and reflecting galvanometer for use in calibrating the instruments.

WINDING DEPARTMENT.

On the upper floor, above the heavy engineering department, is the winding department. This is kept quite distinct from those where any purely mechanical process is carried on to keep the wires from being damaged in any way from flying particles of metal which might damage the insulation and cause short circuits. The process of winding the magnets in coils by the lathe is carried on here, and on the same floor is carried out all the work connected with the armatures of the machines. The steel spindles come

Digitized by Google

from the large shop below, and are fitted with soft iron discs, forming the core of the armature, which are stamped out of the required shape by the stamping machines below. These cores, after being very carefully balanced, are insulated, and then have the winding put on to them. This operation of winding, which, as its name implies, used really to consist of winding comparatively thin wire over the core, now in almost all cases of the larger class of machines consists of fixing on large strips or bands of copper insulated from one another by plates of mica and other insulating material. Great attention has been paid to various systems of building up this winding, so as to enable armatures to be easily repaired when away from the workshop. On this floor quite recently might have been seen the largest armature hitherto constructed in the world for continuous current machines, now at work at Milton, Staffordshire, for supplying current for smelting aluminium direct from the ore by the Cowles' process. This huge armature is in regular work to carry a current of 5,000 amperes, and it is doing its work very satisfactorily. The largest armature shown in the works is that belonging to a slow-speed machine, for a new central station belonging to the Liverpool Electric Supply Company, and is capable of supplying current for 5,000 lamps driven at a speed of 720 revolutions. This dynamo is wound in accordance with a new patent of Messrs. Crompton and Swinburne. The armature has a clear passage through the centre, which admits a perfect ventilation, which had hitherto been considered impossible with this form of armature. Fourteen armatures of approximately the same dimensions as this one have, within the last twelve months, been made in this department, besides a large number of smaller ones. Here can also be seen in course of construction a new form of armature for an alternating-current dynamo, of which great things are expected. It is built to give 2,000 volts and 32 amperes at 400 revolutions per minute without excessive heating, which is a very progressive result considering that this output is nearly eight times that given by a Westinghouse machine of the same size. This dynamo is made according to another patent of Messrs. Crompton and Swinburne, which has lately excited considerable interest, the armature wire being wound in holes, so that there is an unbroken surface of iron, and thus a very small clearance between the armature and the field-magnets. The field-magnets are of purest and softest wrought iron, made out of solid forged ring nearly 3ft. in diameter, turned and then slotted out in recesses to receive the coils.

Draughtsmen's Office.

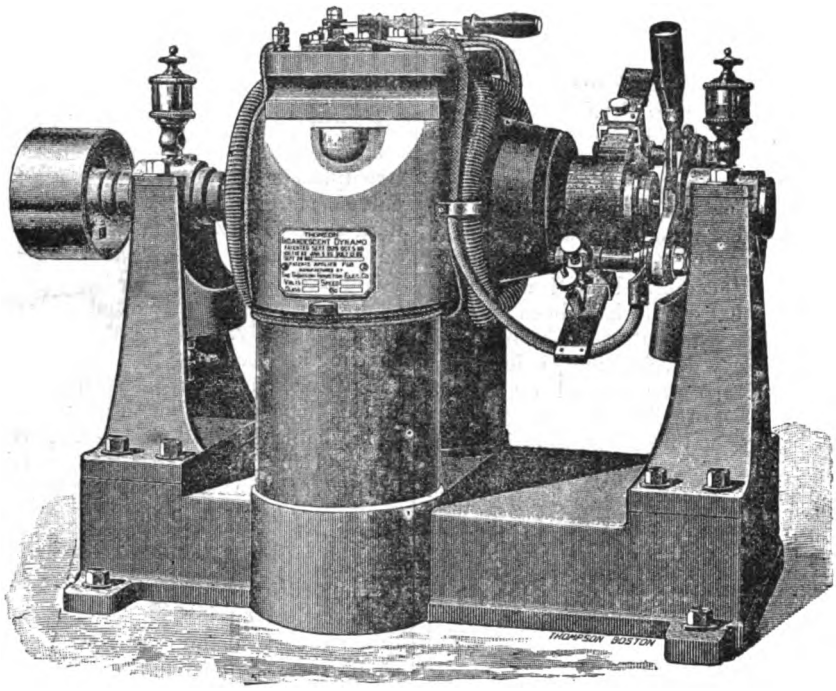
A separate and well-lighted office employs quite a contingent of draughtsmen working out the designs for projected contracts, or making the plans and detailed drawings required in the manifold processes proceeding on the works. Here can be seen plans and details of the Vienna central station, the apparatus for Whitehall, tramcar work, new dynamos, electric cranes, gun training apparatus, plans for public building and private house lighting in profusion.

A number of very interesting examples of electrical engineering at present in progression at Messrs. Crompton's works, with experiments, were shown, consisting of the giant switchboards for the Whitehall accumulator system installation; automatic accumulator cut-out; a new and special gun-training apparatus, worked by electric motors, travelling either right or left on a radius, and elevating or depressing the gun at will, by the action of two small electro-motors, easily controlled from one handle; an electric crane for the roof of a warehouse, for unloading timber, which will raise one ton 8ft. per minute, travelling, slewing, and hoisting, by means of an electric motor. These we shall describe next week with full illustrations.

(To be continued.)

NEW THOMSON-HOUSTON DYNAMO.

This new dynamo, the illustration of which is given by the New York *Electrical Review*, possesses many valuable features. It is made shunt-wound, to supply a demand for a machine for the charging of storage battery cells, and series shunt-wound for direct lighting. This machine is perfectly automatic in its regulations, so that any load can be carried from one lamp to the full capacity of the machine, and lamps may be turned on and off without readjustment of the brushes, or giving the dynamo particular attention. Every part is proportioned for durability and simplicity. The commutators and brushes are easy of access. It is compact, and occupies small floor space.



New Form of Thomson-Houston Incandescent Dynamo.

THOMSON'S NEW ELECTRIC WELDING APPARATUS.

For the last few months work has been actively pushed in the factory of the Thomson Electric Welding Company, at Lynn, Mass., in the perfection and standardising of apparatus employed in the ingenious electric welding process of Prof. Elihu Thomson. This work has now so far progressed that the company is ready to supply machines for electric welding, and the new form of the machine is shown herewith.

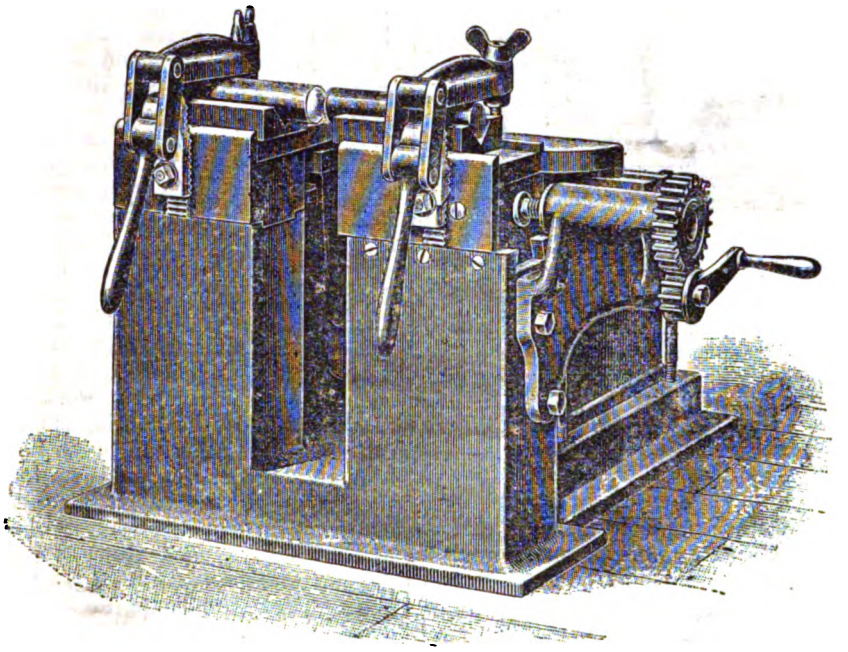
The illustration represents what has been named the "in-

Digitized by Google

direct" welding machine. In this an alternating current is supplied to a converting coil placed within the case, and fed from a dynamo at a distance, the high tension current being transformed into one of low tension and of large volume. The front of the iron case carries adjustable clamps at the top, between which the pieces to be welded are fastened, and a crank at the right hand serves to screw the pieces into firm contact to effect the weld. By employing the converter, the machine becomes very light for its power, so that it may be placed in any convenient location more or less distant from the dynamo and engine. The machine illustrated is designed for moderately heavy work, such as welding metal bars up to about two inches in diameter.

The "direct" welding machine is another form, combining both the dynamo and welding apparatus, and consists of a machine having two windings on its armature. One of these windings gives an alternating current, which is taken off by two wide brushes bearing against collector rings, seen directly under the welding table. The alternating currents are led directly to the welding clamps, and are under the control of the switches at the left-hand side of the table.

The other winding on the armature is connected to the commutator placed at the front end of the machine, which rectifies the current for the excitation of the field-magnets. By means of this arrangement the strength of the welding current can be regulated to a nicety by varying the strength of the field-magnets, which is accomplished by shifting the brushes by means of the handle attached to the brush-holder, which is provided for that purpose.



Latest Form of Thomson's Welding Machine.

This machine is designed for all kinds of light work, its capacity, however, ranging from fine wire to rods 2½in. in diameter.

It has been found that the power required for the different sizes varies nearly as the cross sectional area of the material at the point where the weld is to be made.

By the use of these machines an endless variety of work can be performed, not only in welding pieces of like or different material, but also in shaping, bending, forging, and tempering metals. Welding is destined to be one of the greatest of the electric arts.—*Electrical World.*

AERATION CURRENTS.

Dr. C. R. A. Wright and Mr. C. Thompson, in a recent paper before the Royal Society, of which an abstract is given in the Chemical Society's *Journal*, state if different aëration (spongy and smooth platinum and gold) plates are placed above the same oxidisable metal in dilute sulphuric acid or aqueous potash, and left until a constant aëration is obtained, and if they then are connected together, a current is set up, which lasts with decreasing intensity for several days, and which at starting has an E.M.F. equal to the difference between the E.M.F.'s obtained by exposing each plate to the oxidisable metal. The passage of the current electrolyses the sulphuric acid, with the result that the aëration of the positive plate is reduced, whilst that of the negative plate is increased. If the current is interrupted for some time, the plates recover their original aëration. With silver plates in sulphuric acid, acetic acid, and aqueous ammonia, a stronger current is obtained, the silver passing into solution; moreover, the amount of silver deposited in a voltameter by the current is less than that dissolved in the cell. The difference is greater with feeble than with strong currents. If the silver is opposed to a powerful oxidising agent such as platinium in nitric acid, the current produced is stronger, but the discrepancy between the quantity of silver dissolved and that deposited remains.

Other metals dissolve in the same way, thus mercury opposed to an aëration plate gives mercurous sulphate. Gold in potassic cyanide gives potassium auro-cyanide. Palladium behaves in a similar manner. If platinum in chromic acid is substituted for the aëration plate, gold can be dissolved in hydrochloric acid, forming aurous chloride which subsequently decomposes.

GAS COMPANIES AND ELECTRICITY.

Our energetic friends connected with the gas interest are determined to keep well before them the question of competition between gas and electricity, and a paper on this subject was recently read at the Ohio Gas Light Association by Mr. F. W. Day. After discussing general questions, the author of the paper went on as follows:—

"The sceptical will no doubt, 'What has all this to do with us?' Let us see. 1st. The introduction of an incandescent plant into the business district of a town means the loss of the gas consumption of at least one 5ft. burner for each incandescent lamp used. 2nd. The cost of a plant would depend largely on whether the direct current three-wire or the alternating system were used, and this, as also the cost of running it, would depend on the circumstances under which the plant was to be operated—the distance of the lamps from the station, the difference in the commercial efficiency of the generating apparatus, all coming in for due consideration. We will suppose that the system requiring the least capital was embraced—we are told that the amount of investment, including land, buildings, steam plant, and complete generating and distributing

Digitized by Google

apparatus erected and ready for use, would average 25dols. per lamp. Adding 10 per cent. to this as a factor of safety, would make a 1,000-light cost 27,500dols.

"The third question requires more in reply. We will take, for example, a plant located in a town, the business portion of which would use 1,000 16-candle lamps. With a 16-candle per 5ft. gas, selling at 1dol. 50c. per 1,000 cubic feet, taking four hours as the average daily usage, the total consumption displaced per month would be $1,000 \times 5 \times 4 \times 30 = 600,000$ cubic feet, which at 1dol. 50c. per $1,000 = 900$dols., or an average of 90 cents per month per burner. Allowing for leakage a little less than 8 per cent., the net profit on the gas sold at that rate to pay 10 per cent. on the capital invested would be 55 cents per 1,000 cubic feet, or 3dols. 30c. per month of 30 days. This would be the net reduction of the profits accruing to the gas business resulting from the introduction of 1,000 incandescent lamps, if current was supplied from 6 p.m. to 6 a.m. Now suppose the lamps were furnished at the cost of a 5ft. tip—namely 90 cents per month—the income from the 1,000 would be 900 dols. per month. No meters being used, the charging consumers with the cost of renewals of lamps, the company guaranteeing them to last 800 hours, would have a tendency to limit the hours of use to those specified in the contract; but they would still burn them more than they did the gas jets." Mr. Day estimated that the hours of use averaged 5·4 hours per days. "They would cost," Mr. Day continued, "with a consumption of six pounds of coal per h.p., and an average efficiency of eight 16 c.p. lamps per h.p., with coal at 2dols. per ton:

125 h.p. 4 hours = 125 × 4 × 6 =	1,500lb.(?)
50 ,, 2 ,, = 50 × 2 × 6 =	600 ,,
12½ ,, 12 ,, = 12½ × 12 × 11 =	1,650 ,,
Coal used for banking and starting fires	350 ,,
Total	4,100 b.

4,100lb. at 10 cents per cwt.	$4 10
Water, at 30lb., per h.p. per hour = 2,644 galls., at 50 cents per 1,000 galls.	1 35
Proportion superintendent's salary	2 00
Engineer and station man	3 00
Fireman	2 00
Day watchman	1 65
Lineman and helper	2 50
Repairs to engines, boilers, and dynamos, at 5 per cent. on investment	15 00
Oil	1 00
Interest, insurance, and depreciation, at 16 per cent.	12 25
Taxes	60
Making total daily expenses	$32 00
For average month	32 × 30½ = $976 00

"The income being 900dols., this would make a net loss of 76dols. per month. If placed at 90 cents for those used until 10 o'clock, at 1dol. for those used until 12 o'clock, and at 2dols. 70c. for those until 6 a.m., which would be the cost of a 5ft. gas-burner burned all night, the total income would be 1,060dols. per month, less 976dols. expense, would leave a net profit of 84dols. per month, or 1,008dols. per annum, a little less than 3¾ per cent. on the capital invested. A plant under these circumstances would hardly be called a bonanza. In cases where, as Mr. Wood suggested, the waste heats could be used to such an extent as to save 50 per cent. of the fuel, and the balance could be made up of coke breeze, costing 1 cent per bushel to handle, the expense of firing would be reduced at least one-half, making the whole cost of production per day:

For fuel, 2,050lb., at 1 cent per bushel	$0.52
Other expenses	27.42
Total	$27.94

In round numbers, 28dols. × 30½ = 854dols. for average month. With an income of 1,060dols., and an expense of 854dols., we have a profit of 206dols. × 12 = 2,472dols., or nearly 10 per cent. per annum on the capital as estimated by the Westinghouse people. By the operation of an arc plant in connection with the incandescent, some of the items would be divided, making net earnings considerably larger. The cost, as estimated here, is no doubt larger than it would be placed at by the electrical engineers, but we had better err on the safe side. The manufacture of a cheap fuel gas made use of in gas-engines, together with the advantages of cheap and efficient storage batteries or accumulators, would lower considerably the amount of first investment, and at the same time cut down immensely the cost of production. However, it will not be long now until our energetic hosts will again be able to give us the benefit of their experience with their new venture, they being now engaged in putting in an incandescent lamp. It would seem, from the figures here given, that gas companies are much more favourably situated for furnishing both arc and incandescent lights, or electric currents, than anybody else; and that they should pursue the policy of fortifying themselves in their present positions by obtaining authority so to do—if necessary. Keep an eye on the public pulse, and if they will have it, give it them. By so doing they would make a powerful ally of what might, under some circumstances, be a formidable foe. Failure to occupy a field of action in advance of others sometimes results in disaster."

BRUSSELS EXHIBITION.

Though the electric light is largely employed for the illumination of the Exhibition buildings and grounds at Brussels, it does not appear, in the conception of the original scheme, that this very efficient aid to a successful exhibition was sufficiently considered and provided for. Hence, although gas was extensively laid on, it was found after the date at which the Exhibition should have been opened to the public that a very large increase would have to be made in the plant for electric lighting. It is a matter of regret that arrangements for the electric lighting did not form part of the original programme of the committee, as they have thereby missed an opportunity of bringing together in one place a most interesting exhibit, showing the advances made by the several representative companies who have taken to Brussels examples of various forms and types of electrical apparatus, but which, owing to their being distributed in various parts of the Exhibition where the public are least likely to find them out, receive very little notice, and the results of comparison are to a great extent lost. The interior of the Exhibition is principally lighted by arc and incandescent lamps supplied and maintained by Messrs. Thomson-Houston, Shuckert, and L'Electrique, a Belgian company working on the Brush system. In the grounds the lighting is divided between H. Pieper and the Anglo-American Brush Electric Light Corporation, Limited. Pieper's installation has been working some time to a partial extent, but owing to there being a deficiency of boiler power, the total number of lamps installed have not been regularly at work. The Anglo-American Brush Electric Light Corporation, Limited, have 58 lamps of 2,000 c.p. in operation every evening. These are distributed as follows: Ten in British section, six at the switchback railways, six on the high mast opposite the entrance from the Rue de la Loi, and 18 on independent masts all round the grounds. Eighteen lamps are set apart for the illumination of the arena, which was originally intended for the performances of the hippodrome. These, however, came to an abrupt termination, but the lamps are still there, and effect a very useful purpose, as they light up a large space which is the principal thoroughfare from the exhibition buildings to the grounds, and bring into relief one of the most beautiful architectural features of the Exhibition.

BALANCING MOVING PARTS.

A very pretty little controversy is going on in the American technical press on the balancing of moving parts. Prof. Sylvanus Thompson is evidently not a name to conjure with in America. At any rate, here is a man to set him right (though he thinks it "hardly worth the while") on a fundamental point, to whom the position is obvious after an hour's experiment. Mr. Charles Seymour, dating from Defiance, O., writes as follows to the editor of the *Electrical World*, New York:—

"Sir,—In your issue of December 17th, 1887, in an article by Prof. Sylvanus P. Thompson occurs the following sentence: 'Every engineer worthy of the

Digitized by Google

name knows that a thing so balanced as to stand in any position is not necessarily balanced for running; that a four-pound weight at three inches from the axis of rotation, though balanced statically by a one-pound weight at 12in. from the axis, is not balanced by it dynamically, for the moments of inertia about the axis are not equal. On the contrary, a four-pound weight at 5in. is balanced by a one-pound weight at 10in. from the axis.'

"It is often difficult to find the springs which prompt to controversy. Perhaps we are not answerable for the motives. When a man stumbles physically, we help him up. If he stumbles mentally, we are barbarously apt to goad him And why? Because it sometimes affords us amusement to indulge in the psychological exercise of tracing, or of endeavouring to trace, the paths by which the human mind gets astray in a labyrinth of error. But it is hardly worth the while. That Prof. Thompson is in that position is obvious to any man or boy who has experimented an hour with lever and weights and has reasoned on their functions. He needs no other apparatus than these simple elements to show all there is of the law of virtual velocities, all that exists of the ties by which the busy universe is kept in equilibrium, and all that is needed as a compass to lead him back into proved and well charted fields.

"A rotating body, balanced 'dynamically,' is balanced statically. There are machines for practically proving this in nearly every principal town in America And some of those machines are proving a hundred times a day that a rotating body balanced at one rate of speed is balanced for all rates of speed.

"What there may be of an intermittent character in the shape of electrical resistances in a dynamo, as to produce troublesome jars while running, is not now brought into question. The vibrations or jarring caused by the unbalanced rotating parts of machinery are owing, not to the centrifugal force of excessively heavy portions, but to a striving, as of all rotating bodies, to assume rotations upon their centres of gravity. If it be desired that a rotating body run smoothly without jarring its adjuncts, its qualities must be the same as those of a body rotating in space, having a mechanical centre upon which it is desired it shall rotate and a mechanical plane in which it is desired it shall continue. Now this is not difficult to understand, and it is so fortified by mathematics and by mechanical experiment as to be impregnable.

"'A thing so balanced as to stand in any position is not necessarily balanced for running,' says Prof. Thompson. It is only by running that the centre of gravity of any mass can be mechanically found. There must be a *running* in some degree; if not that of complete rotation, it must be that of complete oscillations in arcs of circles like those of scale beams and levers. When by such means the centre of gravity of a mass be found, and the mass be poised thereupon, it can be rotated in any plane, and at any degree of velocity, and cause no more disturbance to its supports than when standing still. This has been proved in practice during every working hour for years, and is so axiomatic as to seem tame. Yet it proves that 'a 4lb. weight at 3in. from the axis' and 'a 1lb. weight at 12in. from the axis' *have* equal moments of inertia, and balance each other under all conditions of rest or revolution."

The question is taken up by Prof. William A. Anthony, of Manchester, Conn., who replies as follows:—

"Sir,—In your issue of June 16 I find a letter from Mr. Charles Seymour, in regard to a rotating body, in which a quotation is made from Prof. Silvanus P. Thompson, to which the writer takes exception. It seems to me that both Prof. Thompson and the writer are wrong in this matter, if I understand them both. Prof. Thompson is right, and the writer is wrong, in regard to the moment of inertia of bodies at different distances from the axis; the moments of inertia of the same body at different distances from the axis are as the squares of the distances, but both Prof Thompson and the writer are wrong in supposing that the moment of inertia of a body has anything to do with the balance of the body, either statically or dynamically, except when the body has an increasing or diminishing velocity. If the body be rotating with uniform velocity, the moment of inertia has nothing whatever to do with its balance. The writer is correct in saying that a rotating body balanced dynamically is balanced statically, always supposing the motion uniform; but the converse of this proposition is not necessarily true. A body balanced statically is not necessarily balanced dynamically; but it is not for the reason that Professor Thompson states, but for an entirely different one. To illustrate: Suppose a long cylinder made up of thin discs; suppose that one of the end discs is heavy on one side of the axis and all the others are exactly balanced; if this cylinder be placed upon straight edges it will of course appear out of balance in consequence of the error in that one disc; there is nothing, however, in the action of the cylinder on the straight edges to indicate which of the discs is out of balance, and suppose that the workman, in order to balance it, places a counter weight at the opposite end of the cylinder from the disc that is the cause of the trouble. Then, when the cylinder is made to rotate, it will appear more out of balance than before. In other words, to obtain a perfect running balance, the cylinder should be in exact equilibrium in every plane perpendicular to the axis. And this is a most important point to be considered in the balancing of the armatures of dynamos. I saw not long ago an attempt made to balance a dynamo armature by putting a counter weight in the pulley at the end of the armature shaft. The effect was to make the jar due to the running of the machine greater than before, very much to the surprise of the workman who balanced it. The cause of the want of balance may have been at the further end of the armature from the pulley. I have been led to write you in regard to this matter because I have found in actual practice that very few men understand the necessity of determining where a balance weight should be applied in order to give a correct running balance. In balancing pulleys that are usually very short in comparison with their diameters, a good result generally follows from placing the counter weight anywhere opposite the heavy side, as indicated by balancing the pulley on straight edges. But in balancing a cylinder like the armature of a dynamo, the problem becomes a great deal more difficult one, and it is necessary to determine not only on which side of the axis the counter weight must be placed, but in what part of the length of the armature."

LEGAL INTELLIGENCE.

EDISON AND SWAN UNITED ELECTRIC LIGHT COMPANY LIMITED, v. HOLLAND AND OTHERS.

Mr. Justice Kay, in the High Court of Justice (Chancery Division), on Monday, delivered judgment in this action, which is one of the highest importance on the subject of electric lighting patents. The trial occupied the time of the Court for no less than 21 days, his Lordship reserving judgment at the conclusion of the arguments. The action was by the plaintiff company to restrain an alleged infringements of their patents by the defendants, Mr. William Holland, late manager of the Albert Palace, Battersea (where incandescent lamps had been used which, it was said, were substantially the same as those protected by the plaintiffs' patents), the Jablochkoff and General Electricity Company, Limited, who had supplied the lamps used at the Palace, and the Anglo-American Brush Electric Light Corporation, Limited, who were the manufacturers of them and had entered into an agreement with the Jablochkoff Company to indemnify them against the litigation. The patents upon which the plaintiffs sued are the same as those they succeeded in maintaining in the Court of Appeal last year, in two actions by them against Messrs. Woodhouse and Rawson—namely, the Edison patent, No. 4,576, of 1879, for the incandescent lamp, and the Chesebrough patent, No. 4,874, of 1878, for a mode of making uniform the carbon filament or thread which forms the light-giving portion of the lamp. The cases against Messrs. Woodhouse and Rawson will be found reported in the *Times* of May 23, 1886, and February 13, 1887; also in the *Times* Law Reports, Vol. II., pp 654—656; and Vol. III., pp. 327, 367. During the delivery of Mr. Justice Kay's judgment, which occupied nearly an hour and a quarter, the court was crowded to excess with persons of eminence in the scientific world, besides the general public. As will be seen from the judgment, his Lordship gave a highly interesting account of the processes in the gradual development of the incandescent lamp, a method of electric lighting now in use in the Royal Courts of Justice, and numerous other public buildings.

The Attorney-General (Sir R. Webster, Q.C.), Mr. Aston, Q.C., Mr. Moulton, Q.C., and Mr. A. M. Bremner appeared for the plaintiffs; and Sir Horace Davey, Q.C., Mr. Finlay, Q.C., and Mr. J. C. Graham for the defendants.

Mr. Justice Kay said: The plaintiffs sue the defendants for infringing two letters patent; one Edison's patent, No. 4,576, of November 10, 1879; the other, Chesebrough's patent, No. 4,874, of 1878, amended by disclaimer dated the 12th of November, 1884. Both patents relate to electric incandescent lamps. The defence is taken up

Digitized by Google

by third parties, the Anglo-American Brush Electric Light Corporation. The validity of both patents is put in issue. The first thing necessary is to ascertain, as accurately as is possible, to anyone who has not had the necessary scientific training, what was known on the subject at the date of these patents, say, in 1879. There are two commonly known systems of electric lighting—the arc and incandescent systems. These patents relate to the latter. The former depended upon a break in the conducting material occurring at a point where the conductor was carbon in the form of a pretty thick pencil. The current leaped over the break in an arc, gradually destroying the carbons; and this arc gave a vivid white light, especially at the positive pole. The incandescent system is different. The conducting material in this is continuous, without any break or actual interval; but, being in part an imperfect conductor, that part becomes heated to its resistance to what is called the passage of the current, and this heating, raised to an intense degree, gives the light now familiar to us in the incandescent lamp. The material which is now so heated is some form of carbon. It was well known that this was a good material for the purpose, because it was an imperfect conductor—in other words, had a high specific resistance—and that it was essential to use it in a vacuum or in some gas or vapour which did not contain oxygen, otherwise the carbon consumed quickly. Until 1872, when Sprengel's air-pump was improved by Mr. Crookes, it was difficult to obtain a vacuum which was complete enough. The consequence was that it was necessary to employ a pencil of carbon of comparative thickness, because there was enough oxygen left within the exhausted glass bulb to occasion some consumption of the enclosed carbon, and also enough air to diminish the bulk of the carbon when incandescent by frictional action upon its heated surface, which Edison in his specification and some of the witnesses have called "air-washing." Another difficulty which prevented the use of very slender carbons was the irregularity of the current obtained from the dynamo. It was subject to variations, which at times produced a current stronger than the carbon could bear. This was remedied by the improvements of Gramme and Brush, which were perfected in the year 1878. Two modes of improving the resistance of the carbon were known, one by increasing its length, the other by the diminution of its thickness—or, to use the more exact language of the witnesses, of its sectional area. It was known that the carbon for an incandescent lamp must be enclosed in a glass bulb from which the air must be exhausted. Bulbs made entirely of glass had been used and publicly exhibited for this purpose. It was known that molten glass could be made to adhere closely to platinum wires, because the glass proper for the purpose expands with heat in the same degree as that metal, and that for this reason and also because of its properties as a conductor of electricity, the best mode of connecting the carbon within the glass bulb with the main wires through which the current passed, was to unite each end of it to a thin platinum wire, and to fuse the glass round these wires so that air should not penetrate at the points at which they entered the bulb. It was known that by increasing the electromotive force the main wires bringing the electric current to the lamps might be reduced in size, just—to take the illustration given by Sir F. Bramwell—as by increasing the hydraulic pressure in the pipes supplying a town with water, you are enabled to use smaller pipes, because the water will pass with accelerated velocity. It was known that by using high resistance in the incandescent portion of the lamp smaller leading wires might be employed, and also a greater number of lamps might be illuminated from the same source of electricity by working them, as Dr. Hopkinson calls it, in multiple-arc or in parallel. Two systems of using incandescent lamps were known, and it was recognised that when many lamps were to be lighted from one central station, and at some distance, the system called "multiple-arc" or "in parallel" was best. That may be shortly described as a plan involving the use of one main leading and one return wire, each lamp being supplied with electric current by a smaller wire from the main leading wire, and returning such portion of the current as it took to the return wire, the main leading wire and the return wire being supposed to be parallel. The other system, which is little employed, was the use of lamps "in series." In this case the whole current is sent through each lamp in succession, and accordingly lamps of comparatively low resistance are required. The *desideratum* in 1879 was to obtain lamps of high resistance for the "multiple-arc" system, which could be made "commercially," that is, in large quantities with reasonable cheapness, and, above all, that should have durability. Edison, Lane Fox, Swan, and others had been working with this object in the same direction. On the 19th of December, 1878, in a lecture given by Swan at Newcastle, he described an experiment on the production of light by passing a current of electricity from a dynamo through a slender rod of carbon enclosed in an exhausted globe. On January 17, 1879, he lectured on the same subject at Sunderland, illustrating his lecture by experiments, exhibiting certain electric lamps. On the 4th of February, 1879, he again lectured at Newcastle, and he then exhibited the lamp which has been produced in evidence. It consists of a bulb made entirely of glass with leading platinum wires sealed into it, and connected with a pencil of carbon inside the bulb. This piece of carbon was obtained from Carré, of Paris, and was manufactured by him and shaped before being carbonised. It is 1-25th of an inch in diameter—that is, considerably thicker than the carbons now used—and, being straight, the leading wires are sealed into the bulb at opposite ends. This renders it liable to a defect which is alluded to in the correspondence between Swan and Mr. Stearn—viz., rupture of the carbon, or its separation from the wires by expansion and contraction under the great heat to which it is exposed. This lamp was exhibited again at Gateshead on the 13th of March, 1879, and seems to have been kept lighted for ten to twenty minutes at a time on two or three occasions without injury. I have no evidence how long it would last if continuously used. Swan, in the spring of 1979, ordered from Carré carbons in the shape of a hair-pin, a model of which he produces. It is practically identical in form with some of the carbons now used in lamps, but with a larger sectional area. Lamps made with these would not have the defect to which I have alluded. He says that probably towards the end of 1879 he made some lamps with those hair-pin carbons. They are referred to by Mr. Stearn in a letter dated the 26th of November, 1879, in which Fig. 2 is a sketch of a lamp so mounted, but I do not lay much stress upon this as an anticipation of Edison, for, although Heaviside and other witnesses speak of having seen these lamps in 1879, I think the fair result of this evidence is that these were experiments which did not succeed in producing a commercially successful result before Edison's patent. On the 2nd of January, 1880, Swan obtained a patent for one of the most valuable inventions connected with the manufacture of incandescent lamps. That was for preparing the carbon by passing the electric current through it, and heating it to incandescence while the bulb was still connected with a Sprengel air-pump in action. This is now always done, and the effect is to make the vacuum much more perfect, or, rather, less liable to be impaired by air or gas coming from the carbon itself when first heated in a vacuum. On the 21st of January, 1880, he obtained a patent for a horse-shoe strip of cardboard prepared for an incandescent lamp by converting it into a substance like parchment by treatment with sulphuric acid and then carbonising. On the 27th November, 1880, he obtained a further patent for the application of this process to cotton thread. This has proved a most valuable invention. It produces a non-structural tough material, said by one of the witnesses to be hard and stiff as a metallic wire, and this is now largely used for incandescent lamps. Mr. Edison applied to the object of producing a lamp of high resistance his untiring and apparently inexhaustible ingenuity; but his specification shows—as Sir F. Bramwell states—that he was not aware how much was actually then known to electricians like Lane Fox and Swan, and Edison conceived that he was the first inventor of some matters in which they seem to have anticipated him. Edison availed himself of the more perfect vacuum obtained by the Sprengel pump, and also of the known principle of increasing the resistance of the carbon by diminishing its sectional area, which had become possible to a much greater degree owing to the perfecting of the Sprengel air-pump and the dynamo. The most important point raised upon the construction of his patent of November 10, 1879, is the extent of the second claim—whether it includes every lamp of the kind there described, the light-giving carbon in which is a "filament"; or whether it means only lamps with such filaments as are particularly mentioned in the body of the specification. Another point is upon the first claim, whether the word "lamp" in that claim does not mean merely the filament of carbon. A third question of construction is whether the carbonisation of the filament is to be effected before or after it is attached to the platinum wires. With respect to the sufficiency of this specification, it is urged that Edison ought to have defined exactly what was meant by the word "filament," and that his patent of 1879 is void for insufficiency of specification in this respect, and also because it does not give sufficient directions for carbonising filaments. None of the modes of making filaments particularly described, it is said, are practical; or, at any rate, some are not, especially the several modes of making filaments from a putty composed of lamp-black and tar, and from that putty compounded or coated with various substances. Also, if the patent means that the filament is to be carbonised after being attached to platinum wires, this, it is said, is impracticable because the platinum wires would thereby be made porous and brittle, and could not be sealed into the glass so as to prevent air getting in at the point of sealing, or through the pores in the wire. His Lordship then referred to "Neilson v. Harford" (8 "M. and W.," 806) and "Simpson v. Holliday" (13 "W. R.," 578, "L. R." 1, H. L., 315) as to the proper mode of construing a specification, and proceeded: With regard to the construction of Edison's patent, No. 4,576 of 1879, I observe, first of all, that the provisional specification begins by stating the necessity that lamps connected in multiple should be employed without main wires of great size, and that it is essential that these lamps should have a high resistance. It is stated that this had been set forth in a previous patent of Edison's of the same year, and that lamps of great resistance had been obtained by a long wire of platinum or other metal pyro-insulated (which means coated with an incombustible substance) and coiled so that but small radiating surface was exposed. Then it is said that the present invention relates to lamps of a similar character, except that carbon threads or strips are used in place of metallic wire, and connected to platinum wires sealed into a bulb exhausted of air. A description of the mode of manufacture is then given, but not in so much detail as in the complete specification. Turning to that, I find that it commences with a short statement that the object of the invention is to produce incandescent lamps of high resistance. Then follow four paragraphs stating in what the invention consists. The first of these is the coiling of carbon wire or sheets so as to offer great resistance and present but a slight surface for radiation. The next the placing of such light-giving body of great resistance in a nearly perfect vacuum. The third states that the connecting wires are platinum sealed into the glass. The fourth is the method of manufacturing carbon conductors of high resistance, and securing perfect contact between them and the wires. The specification next states Mr. Edison's view of what had been done up to that time. It is admitted that this is inaccurate in many respects. He appears to be have been unaware of the attempts that had been made to do the very thing at which he was aiming—that is, to increase the resistance of the carbon burners in lamps made of bulbs of glass exhausted of air, the connecting wires being made of platinum sealed into the glass. He seems ignorant that bulbs made entirely of glass had been used, or that they had been exhausted of air so as to form a vacuum. His Lordship then read Mr. Edison's description of the several modes of making the carbon burners, and proceeded: Then come the claims, which are four in number—"(1) an electric lamp for giving light by

Digitized by Google

incandescence, consisting of a filament of carbon of high resistance made as described and secured to metallic wires as set forth; (2) the combination of a carbon filament within a receiver made entirely of glass through which the leading wires pass, and from which receiver the air is exhaused for the purposes set forth; (3) a coiled carbon filament, or strip, arranged in such a manner that only a portion of the surface of such carbon conductor shall radiate light as set forth; (4) the method herein described of securing the platina contact wires to the carbon filament and carbonising of the whole in a closed chamber substantially as set forth." I do not agree that the word "lamp" in the first claim means only the "filament of carbon." The claim is, "an electric lamp for giving light by incandescence," which the filament alone could not do. The words "consisting of" are inapt, but the wording of the whole specification is exceedingly inaccurate, and this is only an example of such inaccuracy. "Containing" would have been a better word. I construe this claim to mean lamps such as described in which the distinguishing features are carbons of "high resistance made as described and secured to metallic wires as set forth." After commenting on the other claims, his Lordship proceeded: The claims, as I read them, are—(2) a combination of four requisites for a lamp; (3) and (4) claims for two of those requisites separately; and (1) a claim for particular modes of making and attaching to platinum wires the first item of the combination—viz., the carbon filament. But claim (2) comprehends lamps containing carbon filaments, however made, and not only those made in the special modes described in the body of the specification and included in claim (1). The defendants construct incandescent lamps with all the four elements of the combination described in Edison's second claim. But the filament made by them is essentially different from anything particularly described in Edison's specification. His Lordship then described the defendants' mode of making the filament used by them, and continued: As I have come to the conclusion that Edison's second claim is wide enough to include any lamp wih a carbon filament, however made, the defendants have clearly infringed this claim. Then comes the serious and important question whether so wide a claim can be supported. I have already pointed out that the only item of the combination which had any novelty was the use of the filament or "very slender thread" of carbon. Edison had managed to use carbons thinner than anyone had used previously. The only advantage of a "filament" suggested in the specification is its high resistance by reason of its thinness or small sectional area. There was no invention described in this specification of any new principle. The principle of increasing resistance by diminishing the sectional area of the carbon was known and had been published by Lane Fox and by Swan before November, 1879. Assuming that Edison had been the first successfully to put that principle in practice by the methods described in his specification, did that success entitle him to say "no one shall make a lamp with a filament of carbon but myself?" Suppose the claim had been thus worded—"I have succeeded in making an electric lamp with a carbon burner, say, 1-00th of an inch in diameter, which gives a high resistance, and I claim a monopoly of all lamps with carbon burners but thicker than that, however made." Could such a claim be supported? That, in effect, is Edison's second claim. One of the objections made is that the claim ought to have been worded in some such ways as I have suggested in order to make it sufficiently definite. In other words, Edison ought to have indicated the exact boundary between his "filament" and such a Carré carbon as Swan had successfully used. From the drawings, and from the great stress laid upon coiling the filament, the only object of which seems to be to increase resistance by using a considerable length, I should conclude that Mr. Edison did not conceive that extreme thinness of the carbon was practicable. Mr. Swan had tried paper, cardboard, and similar materials carbonised, and, if he had not tried a "filament," he had used and obtained considerable success with Carré carbons not more than 1-25th of an inch in diameter. He was trying these in the form of a hair-pin, made and shaped to that form before carbonisation; and it seems impossible to say that Edison, by reducing the thickness of the horse-shoe carbon, had made any vast invention or contributed largely to the knowledge which such inventors as Swan and Lane Fox already had on the subject. His Lordship then referred to "Jupe v. Pratt" (1 "Webst.," 146) as an authority on the right of an inventor to be protected on patenting a practical mode of applying a new principle discovered by him, and proceeded: But is there any decision that an inventor who has discovered a mode of applying a known principle like this—of increasing resistance by diminishing the sectional area of the carbon burner—can obtain a monopoly of the principle? Sir F. Bramwell, in his evidence for the plaintiff, put too case in the strongest and most favourable manner by saying that Edison made the first commercially successful incandescent lamp. Unless that is so, his claim to so large a monopoly would not, in my opinion, be arguable. I proceed to enquire—Did he make a commercially successful lamp—that is, were any of the modes of making lamps particularly described in the specification commercially successful. His Lordship then referred to the numerous other electric patents taken out by Edison, and proceeded: The plaintiffs have been challenged again and again during the cross-examination of their witnesses to prove, if they can, that any lamp with a burner made according to the description in the body of the specification of November, 1879, has been brought into the market in England or in America. No evidence of this has been given, and I conclude that there was no commercial use of the invention of that kind. Until he had taken out his subsequent patents it seems that Edison did not introduce any lamp to the public. His Lordship then referred to certain experiments which had been made in constructing lamps under the patent of 1879, and continued: With respect to the commercial success of the invention as tested by these experiments, I find from the report and a supplemental table of results, which has been handed to me as an agreed statement, that out of 100 lamps some broke down at once, 13 lasted less than 10 hours, 11 more less than 20, 18 more less than 40, and only six above 40 hours, of which four were unbroken at 60 hours, and of these four there is no further record. That is far from commercial success. No system of electric lighting could be maintained, except at an expense which could not practically be incurred, with lamps of such short life as these; and this explains most satisfactorily why Edison never sold lamps made according to the specification of 1879. In considering the sufficiency of this specification, it must be remembered that in 1879 there was no trade or business of manufacturing electric incandescent lamps. Lane Fox, Edison, Swan, and other inventors had given much time and attention to the subject, but except such persons there were none who had any special knowledge in the matter. The *dicta* that may be found in some cases that the specification of certain patents must be read as addressed to adepts in the particular trade or business do not apply. For this reason it was essential that the specification should be carefully explicit. It ought to be such as would enable an intelligent working man to make an incandescent lamp without having to try experiments. His Lordship then examined the specification on the question of sufficiency of description, and arrived at the conclusion that it was vague and insufficient. His Lordship then proceeded: My opinion is that the patent of Edison's, No. 4,576, of 1879, is invalid—first, because the second claim is for a monopoly of incandescent lamps containing a filament of carbon for a burner, which claim, I think, is far too wide, considering how little Edison had actually invented; secondly, because his specification does not describe a lamp which ever became, or, as I think, could have become, commercially successful; thirdly, because the directions therein contained are so insufficient that no one could have made the carbons he describes without considerable previous experiment; fourthly, because one of the processes described—namely, mixing the carbon with a volatile powder—I believe to be practically injurious, if done as Edison directs; fifthly, because the coating with a non-conducting, non-carbonising substance, if not injurious, is of no practical utility; sixthly, because the same may be said of coiling the filaments, on which the patentee lays great stress. This patent of Mr. Edison's, No. 4,576, of 1879, has been the subject of litigation in a previous suit between the present plaintiffs and Messrs. Woodhouse and Rawson, who were manufacturing incandescent lamps, and were sued by the plaintiffs for infringements. The case went to the Court of Appeal, and both in the Court of First Instance and in the Court of Appeal the patent was treated as valid, though apparently with some hesitation. I am bound by these decisions, and should follow them, of course, whether agreed with them or not, if the evidence in the two cases were the same. But that is not so. On one point, which Lord Justice Cotton seems to have thought essential, the Courts were completely misled. They were given to understand that the carbon-burner in the lamp exhibited by Swan before the date of Edison's patent was shaped after, and not before, carbonisation. It is now admitted this was not the fact. It was a carbon made by Carré, and used as made by him without alteration. But, further, I am told that there was no evidence in that case as to the difficulty of making the carbon described in Edison's patent from the description in the specification. I understand that no contest took place as to the sufficiency or utility of any part of Edison's patent, and that nothing like the evidence as to the previous knowledge on the subject was given in the trial which has been adduced in this. With respect to the construction of the patent, the opinion which I have expressed agrees with that of the majority of the learned judges in the Woodhouse and Rawson trial. The case has been brought before me with such an elaboration of evidence on every point that I think myself bound to act upon my own opinion, believing as I do that if the same materials had been before the learned judges in the other case they would have arrived at the same conclusion as I had done. The other patent in question in this action is Chesebrough's, No. 4,874, of 1878, amended by disclaimer dated November 12, 1884. The specification describes and claims a method of preparing the illuminating portion of an electric lamp, and also a material for the manufacture of illuminating carbons. Shortly stated, the carbon to be prepared is surrounded with a carbon gas or liquid and then heated intensely by the passage of the electric current. This causes a decomposition of the surrounding hydrocarbon, and the deposit upon the heated surface of an extremely dense form of carbon, such deposit being in greater quantity upon the hotter—that is, the thinner—portion. The specification states that "carbon of the ordinary sort when heated by the electric current, exhibits points and lines of unequal brilliancy. Carbons prepared by the process when so heated glow with a uniform brilliancy throughout." A French chemist, Despretz, in experimenting on the reduction and volatilisation of carbon, discovered that when the carbon was heated in an atmosphere of hydrocarbon this deposit occurred and interfered with his operations; and he describes this in a paper which was published in England some years before 1879. But Despretz did not utilise this product in any way, and his experiments had nothing to do with electric lighting. Assuming that Chesebrough derived his knowledge of the mode of producing this material from Despretz's paper, his invention consists in applying it for the purpose of making uniform the light-giving power of a piece of carbon when heated by the electric current; and the beauty and merit of the invention consist in thus enabling an imperfect carbon, by a sort of automatic operation, to improve and perfect itself. I have no doubt that this is a good subject for a patent. I had more hesitation upon the claim for the material, which certainly was not discovered by him; but that is not the whole of the claim. It is for "a material for the manufacture of the illuminating conductors of electric lamps produced by electricity heating carbon in the carbon gas." That does not prevent anyone from making the same material and using it for other purposes. The claim is really for the use of the material for the burner of an electric lamp. This seems to me equally valid. Another objection—that pencils cut from the lime cylinder coated with carbon would not make effective carbons—seems to me to arise from a misconstruction of the specification. It is not the lime cylinder, but the deposit of carbon which is to be made in burners. The defendants have used this process at Chesebrough's, but they say for a different purpose.

Digitized by Google

The object is to bring all their carbons to one standard of illuminating power, an operation for which they have invented a somewhat cacophonous word—"standardising." But Sellon, one of their principal witnesses, admitted that the process would cure any inequalities of light-giving surface in the particular carbon so treated. These, he says, in their cellulous carbon threads seldom occur However, I cannot resist the conclusion that the defendants, by this use of the process for carbons of incandescent lamps, are infringing Chesebrough's patent. The plaintiffs' reply in this case was, unfortunately, interrupted. The Attorney-General asked leave, if the Court wanted more assistance on any point, to add somewhat to the reply. I have not thought it right to trouble him further. Every point has been put again and again to the scientific witnesses. Twenty-one of the working days of the Court have been occupied by this case. I have not arrived at the conclusion I have intimated without thought and care, and I do not think that further argument would be a useful expenditure of public time. I must, therefore, decline to trouble counsel any more in the case. I have been provided with a copy of the print of the shorthand notes. They contain, as is, perhaps, inevitable in such a case, a considerable number of verbal inaccuracies, some of which completely distort the meaning of what was said. The action, so far as it relates to Edison's patent of 1879, must be dismissed with costs. There must be an injunction to prevent any further infringement of Chesebrough's patent, and the defendants must pay the costs of the action so far as it relates to that. The costs must be set off in the usual way.—*The Times.*

THE UNITED TELEPHONE COMPANY v. TASKER, SON, AND CO.

This was an appeal, before Lords Justices Cotton, Fry, and Lopes, against a decision of Mr. Justice Kay. The defendants are the proprietors of a telephone exchange at Sheffield, and the action was brought to restrain the defendants from infringing a patent (known as the Bell patent) for telephones, granted in 1876 to the plaintiffs' predecessors in title. The plaintiffs moved for an interim injunction. The defendants admitted that they were using telephones which were an infringement of the plaintiffs' patent, but they justified their conduct in the following way. They said that they had formed an exchange in Sheffield; that they had done this at the invitation of the plaintiffs' predecessors in title, and under an agreement subject to which the patent was transferred to the plaintiffs. The plaintiffs now refused to carry out the agreement, and refused to supply the defendants with telephones at all; so the defendants made telephones, which they admitted were an infringement of the plaintiffs' patent. Mr. Justice Kay (as reported in *The Times* of the 9th June) said that the defendants, by their conduct, were taking the law into their own hands; because the contract had been broken they took upon themselves to infringe the patent. Their defence was no justification of the infringement; but, at the same time, it was suggested that the contract under which the exchange in Sheffield was formed had been broken by the plaintiffs in a flagrant manner, though that was denied by the plaintiffs. His Lordship granted an injunction until the trial, or further order, to restrain the defendants, their servants, and agents, from making, using, selling, or otherwise disposing of any telephones which were an infringement of the plaintiffs' patent, on the plaintiffs undertaking to supply to the defendants upon the usual terms as to cost, either by way of loan, sale or letting for hire, at their pleasure, so many telephones as the order would prevent the defendants from using, the plaintiffs also giving the usual undertaking in damages. The plaintiffs assented to the giving of this undertaking. On the hearing of the motion it was stated that the defendants were using 52 telephones, which were infringements of the patent. Before the drawing-up of the order was completed, the defendants informed the plaintiffs that they had discovered that they had in use 44 other telephones, which they had purchased from one Paterson, on a representation and a guarantee by him that these telephones had been made under a license from the plaintiffs, and that they had discovered that no license had, in fact, been given. The defendants contended that the plaintiffs' undertaking extended to the forty-four telephones, as well as to the fifty-two. The plaintiffs objected to this, and applied to Mr. Justice Kay to be relieved from their undertaking. Mr. Justice Kay held that the undertaking ought to extend as the defendants desired, and declined to relieve the plaintiffs from their undertaking, except on the terms of discharging the injunction altogether. The plaintiffs appealed.

The Attorney-General (Sir R. E. Webster, Q.C.), **Mr. Aston, Q.C.**, and **Mr. Micklem** (with whom was Mr. Moulton, Q.C.), for the plaintiffs, contended that the plaintiffs were entitled to an injunction in general terms; but said that they were willing to give the undertaking if limited to the fifty-two telephones.

Mr. Ince, Q.C., and **Mr. W. R. Bousfield**, for the defendants, were content to accept the undertaking thus limited; but they said that the defendants never pretended that they had only fifty-two instruments in use—they had from 1,200 to 1,500 in use, and the plaintiffs had alleged that 200 of these were infringements of the patent. The defendants only intended to say that they had fifty-two infringing instruments in use, and they made that statement honestly, and did not discover until after the hearing of the motion that the other forty-four telephones were also infringements, when they at once communicated with the plaintiffs.

The Court allowed the appeal.

Lord Justice Cotton was satisfied that, though the undertaking was given in general terms, it was given upon the understanding of both parties that only 52 telephones which were infringements of the patent were in use by the defendants, to which 52 the undertaking and the injunction would apply. As soon as the blunder was discovered the defendants ought to have consented to a limitation of the undertaking to the 52 telephones, and his Lordship thought that Mr. Justice Kay ought to have been satisfied on the evidence before him that the undertaking had been given by the plaintiffs as applying only to the 52 telephones, and he should have limited the undertaking accordingly. That, his Lordship thought, was the undertaking which the plaintiffs intended to give. He did not say that the plaintiffs were bound to give any undertaking, but they were willing to do so, and they had a right to have the undertaking limited to that which they intended to give. With regard to costs the defendants had made a mistake as to the number of infringing instruments which they were using, and, as soon as they found it out, they ought to have acceded to the plaintiff's desire that the undertaking should be limited to that which they intended to give, and ought not to have compelled the plaintiffs to apply to Mr. Justice Kay. The costs, therefore, of that application and of the appeal must be the plaintiffs in any event.

Lord Justice Fry did not doubt that the mistatement of fact was a bona fide error on the part of the defendants, or that there was no intention to deceive. But when the error was discovered the defendants ought to have assented to confining the undertakings of the 52 instruments which were in the mind of the plaintiffs when they agreed to give the undertaking.

Lord Justice Lopes concurred.

COMPANIES' MEETINGS.

WEST AFRICAN TELEGRAPH COMPANY.

The third ordinary general meeting of the West African Telegraph Company, Limited, was held on Friday last, at the offices, Cannon-street.

Major-General Sir F. J. Goldsmid, C.B., who presided, said that the traffic had not increased to the extent they would have been glad to see, but in other respects he thought they would find that the working had been satisfactory, and the whole line was at that moment in good order and condition. It was stated at the last meeting that there had been some difficulties in the way of realising the subsidy and guarantees until the accounts were placed on a clear footing. Since then the French subsidy had been paid up to the end of 1887, and the Portuguese guarantee had been paid up to the end of September last. There was, therefore, every reason to suppose that those payments now would be regular. With reference to the traffic, statistics for the complete line were available from September, 1886, but it would hardly be fair to compare the first three months' working of the complete line with the corresponding period in 1887. Taking, however, the first five months of the present year, and comparing the number of words with that of the corresponding period of 1887, after making due allowance for the loss resulting from the interruption on the St. Thomé-Loanda section, they might fairly consider that the volume of traffic had increased at least 15 per cent. For the present they must rely on their guarantee and subsidy, hoping for better results in the future, when the system was connected with the Cape; and Mr. Matthew Gray, of the Indiarubber, Guttapercha, and Telegraph Works Company, had sent him a letter stating that that Company was working earnestly towards completing the section from Loanda to the Cape, and that they had every hope that the connection would be made by the end of the year. He concluded by moving the adoption of the report and the payment of a dividend of 3s. a share.

Sir Henry C. Mance seconded the motion, which was unanimously adopted.

The appointment of Mr. E. March Webb as a member of the Board was confirmed, and the retiring Director and Auditors were re-elected.

At an extraordinary meeting held afterwards a resolution was passed correcting an error in the articles of association.

WESTERN COUNTIES AND SOUTH WALES TELEPHONE COMPANY.

An adjourned meeting of the shareholders of the above Company was held on Thursday, July 12, at the Royal Hotel, College Green, Bristol, for the purpose of sanctioning the raising of additional capital to enable the Company to carry out contemplated extensions. Mr. Charles Nash presided.

Mr. H. F. Lewis, secretary and general manager, having read the notice convening the meeting,

The **Chairman** said it had been thought desirable to defer the arrangement for issuing a further amount of share capital, so that the first resolution attached to the report was withdrawn, and he now moved the second resolution, which was as follows:—"That the articles of association be altered in manner following—that is to say: (A) The following article shall be substituted for Article 71—namely, 'They may borrow any sum or sums of money on such security and terms as to interest, or otherwise, as they may deem fit, and may secure the same by mortgage or other debentures, or by bonds or other securities, or by any mortgage or charge of, or upon, the whole or any part of any property, funds, assets, or effects of the Company, or its uncalled capital; but so that not more than £20,000 be owing at any time without the consent of a general meeting, and provided that no part of the said sum of £20,000 shall be borrowed without the consent of the United Telephone Company, Limited, and no borrowed money shall, without the like consent, carry interest at a higher rate than 6 per cent. per annum.' (B) In Article 91 the word 'and' coming after the word 'agencies' shall be omitted, and the words 'trunk lines and new business' shall be inserted after the word 'branches.' The clause as amended shall apply as from the formation of the Company." The sum mentioned (the Chairman continued) might be sufficient to carry them through the present year, and they hoped that money would be obtained at a

Digitized by Google

lower rate of interest than if share capital had been offered—probably not exceeding 5 per cent. He would just repeat what he thought he said at the last meeting—viz., that it was necessary they should have further capital in hand to enable them promptly to cover some further portion of the large district which formed the territory of the Company. It would be their duty very carefully to select from the long list of places mentioned in the report those that were likely to give them a speedy return, and to arrange for opening exchanges in them, and also for connecting them, where desirable, by trunk lines. The only other point, he thought, was that it would not be necessary to borrow the whole of this money at once. That would be done at intervals as required. The last clause of the resolution was only inserted for the purpose of removing ambiguity and making the meaning of the clause plain. There had been a doubt as to whether it included trunk lines or not, and there would be no doubt about it any longer, as these words made the matter perfectly plain. He would only add that the general progress of the company continued to be very satisfactory, and that from week to week they were getting considerable accessions of business. Since they last met there were two places where arrangements were now in progress for speedily opening exchanges — he referred to Cheltenham and Swindon. Perhaps they might not be very valuable in themselves, but Cheltenham, when connected with Gloucester and the Stroud district, and Swindon, if connected with Bath and Bristol, would, he believed, bring a very considerable increase to their business.

Mr. Mark Whitwill seconded the motion, which was carried unanimously.

The **Chairman** said he should like to supply an omission he made at the annual meeting in June by expressing what he was sure was the feeling of the Directors, their high appreciation of the great energy and ability of Mr. Lewis, the general manager. During some very heavy work that had been going on lately, Mr. Lewis had been very ably supported by the members of the staff. They had often had to work long hours. That they had done willingly, and he thought it was only due to them that it should be mentioned.

Mr. Henry Fedden said he had seen a great deal of Mr. Lewis's work and would like to confirm what the Chairman had said in regard to it. He never knew a man who was more earnest in his work than Mr. Lewis, who had shown a thorough determination to make the Company a success.

Commander D. M. Forsyth, R.N., also testified to the great help which Mr Lewis had rendered, both in the formation of the Company and in its subsequent development.

Mr. Lewis briefly returned thanks and the meeting terminated.

NEW COMPANIES REGISTERED.

The Barnoldswick Gas and Light Company, Limited.—Registered by Waterlow Brothers and Layton, Birchin-lane, E.C., with a capital of £12,000, in shares of £10 each. Object: To adopt and carry into effect an agreement, dated May 9, 1888, and made between Christopher George Bracewell Smith Smith and Joseph Henry Threlfull of the one part, and George Kendall of the other part. To manufacture, sell, and supply gas and any other illuminating power in the parish of Barnoldswick, in the county of York, and generally to carry on the business of gas manufacturers and gas fillers, electrical engineers, and every other business in any way connected with the manufacture and sale of gas and electricity or other illuminants. The first subscribers are:—

	Shares.
H. Slater, manufacturer, Barnoldswick	120
J. Pickup, general dealer, Barnoldswick	50
J. Broughton, mason, Barnoldswick	40
J. D. Roberts, physician, Barnoldswick	40
S. Slater, porkbutcher, Barnoldswick	60
C. Brookes, grocer, Barnoldswick	15
J. Hartley, innkeeper, Barnoldswick	20

The number and names of Directors shall be determined by the subscribers to the memorandum of association. The remuneration of Directors shall be determined in general meeting.

The East Strand and District Electric Light and Power Company, Limited.—Registered by the Land Company, Limited, with a capital of £5,000, in shares of £5 each. Object: to apply and obtain, either singly or jointly, licenses, provisional orders, or Acts of Parliament for the supply of electricity; to establish and carry on the business of suppliers of electric energy, of manufacturers of and dealers in electrical apparatus and appliances of all descriptions used or intended to be used in any way in, or which are applicable to, the generation, distribution, storage, measurement, conversion or utilisation of electricity, and the business of an electric light and power company in all its branches, and of engineers and contractors, and such other business as the Directors of the Company for the time being may consider desirable for the interest of the Company. The first subscribers are:

	Shares.
J. Dunn, F.R.I.B.A., 1, John-street, S.W.	1
C. E. Lloyd, 4, King's Bench-walk, E.C.	1
A. W. Lightbody, 222, Strand, W.C.	1
S. H. Burbury, 1, New-square, Lincoln's-inn, W.C.	1
E. Wilson, 5, Adam's-court, New Broad-street, E.C.	1
A. M. Lloyd, Norfolk House, Victoria Embankment, W.C.	1
J. G. Lorrain, M.I.M.E., Norfolk House, Victoria Embankment, W.C.	1

The company is registered without articles of association, and consequently the regulations of Table A of the Companies Act of 1862 apply.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The traffic receipts of the Brazilian Submarine Telegraph Company, Limited, for the week ending July 13 amounted to £4,582.

West African Telegraph Company.—The West African Telegraph Company, Limited, announce a dividend of 3s. per share, payable at the National Bank of Scotland, Nicholas-lane.

Indiarubber, Guttapercha, and Telegraph Works Company.—The Directors of the Indiarubber, Guttapercha, and Telegraph Works Company, Limited, recommend an interim dividend of 5 per cent., or 10s. per share, tax free.

West India and Panama Telegraph Company.—The estimated traffic receipts of the West India and Panama Telegraph Company for the half-month ending July 15 were £2,525, against £2,398 in the corresponding period of 1887.

Western Brazilian Telegraph Company.—The traffic receipts of the Western Brazilian Telegraph Company, Limited, for the week ended July 13, after deducting the "fifth" of the gross receipts payable to the London-Platino Brazilian Telegraph Company, Limited, were £3,789.

Anglo-American Telegraph Company.—At a meeting of the Board of Directors of the Anglo-American Telegraph Company it was resolved to declare an interim dividend for the quarter ended June 30 of 5s. per cent. on the ordinary stock, and 10s. per cent, on the preferred stock, less income-tax, payable on August 1 to the stockholders registered on the books of the Company July 10, 1888.

Globe Telegraph and Trust Company.—The Directors of the Globe Telegraph and Trust Company have declared a final dividend of 3s. per share, less income-tax, on the preference shares, and of 3s. per share on the ordinary shares, free of income-tax, making, with the previous payments, a dividend for the year of 6 per cent. on the preference shares, and 3½ per cent. on the ordinary shares.

Bankruptcy.—A meeting of the creditors of Luther Hanson, electrical engineer, Halifax, has been held at the offices of the Official Receiver. The debtor's statement of affairs showed assets £1,724. 17s. 4d., and liabilities £4,518. 3s. 8d., a surplus of £206. 13s. 8d. In this estimate, however, the works had been taken as a going concern. The debtor was made bankrupt, no offer of composition being made. Mr. James Duff, of Barum Top, was appointed trustee, with a commitee of inspection.

Direct United States Cable Company.—The report of the Direct United States Cable Company, Limited, for the six months ended June 30, shows that the revenue (still subject to revision), including income-tax refunded, and after deducting out-payments, amounted to £17,507, against £23,571. The working and other expenses for the same period, including income-tax, but exclusive of cost of repairs of cable, amounted to £15,276, leaving £2,231 as the net profit of the half-year, making, with £9,911 transferred from the reserve fund account, a total of £12,142. Three quarterly interim dividends of 2s. each per share, amounting to £18,213, have been declared and paid during the financial year, and a final payment of 2s. per share is proposed, making 2 per cent. for the year, being a total distribution of £24,284.

Anglo-American Telegraph Company.—The report of the Directors of the Anglo-American Telegraph Company, Limited, to be presented to the ordinary general half-yearly meeting of the proprietors, to be held on Thursday, July 26, at 12 noon precisely, shows that the total receipts from January 1 to June 30, including the estimated balance of £2,345 brought forward from the last account, are estimated at £77,579. This amount, however, is subject to revision, dependent upon the result of the lawsuit still pending between this Company and the Paris and New York Telegraph Company. The traffic receipts show a decrease, as compared with the corresponding period of last year, of £19,635. The total expenses of the half-year, including repair of cables, &c., as shown by the revenue account, amounted to £42,189. One quarterly interim dividend of 5s. per cent. on the ordinary stock, and of 10s. per cent. on the preferred stock, was paid on the 1st of May, absorbing £17,500, and a second quarterly dividend of 5s. per cent. on the ordinary stock and 10s. per cent. on the preferred stock will be paid on the 1st of August, absorbing £17,500, leaving a balance of £390 to be carried forward to the next account.

Eastern Telegraph Company.—The report of the Directors of the Eastern Telegraph Company, Limited, for the half-year ended March 31 states that the revenue amounted to £359,706, from which are deducted £87,134 for the ordinary expenses and £38,412 for expenditure relating to repairs, renewals, and laying of cables, &c. The available balance was £259,104, from which have been paid interest on debentures and debenture stock, dividend on preference shares, and an interim dividend of 1½ per cent. on the ordinary shares, leaving £161,384, from which £75,000 has been carried to general reserve. The Directors recommend a final dividend of 2s. 6d. per share and a bonus of 2s. per share, both payable on the 19th inst., making, with three previous payments on account, a total distribution of 12s. per share, or 6 per cent., for the year on the ordinary shares. The balance of £884 will be carried forward. With the object of providing a duplicate and alternative telegraphic service to the Cape, the Eastern and South African Telegraph Company (nearly all the shares of which belong to this Company) are making arrangements with the West African Telegraph Company, under which the existing line of cables along the West Coast of Africa (now terminating at Loanda) will be continued to Port Nolloth and the Cape of Good Hope. The new cables will be worked by the Company as part of the Eastern and South African Company's undertaking.

PROVISIONAL PATENTS, 1888.

JULY 6.

9825. **Improvements relating to switches for electrical purposes.** William Mackie, Turk's Head-yard, Turnmill-street, E.C.

9844. **Improvements in the construction of steam boilers, or generators for the economical generation of steam, either with or without the aid of electricity or electrical heat.** Emma Naomi Barnard, 46, Southampton-buildings, Holborn.

9854. **Improvements in and connected with secondary batteries or electrical accumulators.** Lars Bristol, 70, Chancery-lane, London, W.C.

JULY 7.

9907. **An improvement in electric current and tension meters.** Michael von Dolivo-Dobrowolsky and The Company Allgemeine Elektricitätsgesellschaft, 47, Lincoln's-inn-fields, London, W.C.

9910. **Improvements in and relating to continuous current dynamo-electric machines.** Gisbert Kapp, 70, Market-street, Manchester.

JULY 9.

9926. **Improvements in and connected with ships' compasses.** Thomas Bassnett, 4, Clayton-square, Liverpool.

9927. **Improved electrical make-and-brake switch for charging circuits of secondary batteries, and automatic cut-outs for other circuits.** George Vaughan Fowler and Edward William Lancaster, trading as Fowler, Lancaster, and Co., Temple-chambers, Temple-avenue, London, E.C.

9928. **Improvements in electrical regulators and armatures for dynamo-electric machines and motors.** George Vaughan Fowler and Edward William Lancaster, trading as Fowler, Lancaster, and Co., and Ernest James Penn, Temple-chambers, Temple-avenue, Whitefriars, London, E.C.

9931. **Improvements in recording and repeating speech and and other sounds.** Alan Archibald Campbell Swinton, 75, Queen Victoria-street, London, E.C.

JULY 10.

9991. **Improvements in magneto-electric apparatus.** William Robert Lake, 45, Southampton-buildings, London, W.C. (Wm. Humans, United States.) (Complete specification.)

10,048. **Automatic arrangement for switching accumulators in or out of circuit.** Bernard Mervyn Drake and John Marshall Gorham, 28, Southampton-buildings, Chancery-lane, London, W.C.

10,053. **Improvements in or relating to marine compasses.** Wallace John Reynolds, 166, Fleet-street, London.

JULY 11.

10,088. **Improvements in and connected with primary batteries.** John Vaughan Sherrin, 77, Chancery-lane, London, W.C.

10,092. **Improvements in the means or apparatus for supplying electricity to tramcars or other vehicles.** Alexander Login Lineff, 169, Fleet-street, London.

10,093. **Improvements in magneto-electric calling or signalling mechanism used for telephonic or telegraphic purposes.** Joseph Slater Lewis, 53, Chancery-lane, London.

10,101. **Improvements in ships' compasses.** Joseph Von Peichl, 28, Southampton-buildings, Chancery-lane, London, W.C.

10,102. **Improvements in electric batteries.** William Robert Lake, 45, Southampton-buildings, London. (Lacombe and Co., France.)

10,107. **Improvements in casing used for electrical conductors.** Charles Scott Snell, Culver-park, Saltash, Cornwall.

COMPLETE SPECIFICATIONS ACCEPTED.

SEPTEMBER 7, 1887.

12,111. **Improvements in electric fuses for mines.** William Phillips Thompson, 6, Lord-street, Liverpool. (E. Dumas, Paris, agent for Messrs. Bickford Smith and Co., Cornwall.)

SEPTEMBER 8, 1887.

12,166. **Improved appliances for making and breaking and protecting an electric circuit.** Harold Kingcombe Read, 25, Macfarlane-road, Shepherd's Bush, W.

SEPTEMBER 12, 1887.

12,325. **Improvements in telephonic apparatus.** Wallace Fairweather, 62, St. Vincent-street, Glasgow. (The Western Electric Co., United States.)

MAY 29, 1888.

7805. **Improvements in the method of and apparatus for the production, transmission, and distribution of electric currents.** Herbert John Allis n, 52, Chancery-lane, London.) (Charles Edgar Fritts, United States.)

JUNE 5, 1888.

8223. **A magnetic separator for extracting ferruginous matters from ores and other material.** Alexander Henry Reed, Suffolk House, Laurence Pountney-hill, Cannon-street, Middlesex. (Gurdon Conkling, United States.)

JUNE 9, 1888.

8457. **Improvements in mechanical telephones.** Lemuel Mellett, 55 and 56, Chancery-lane, London.

JUNE 12, 1888.

8596. **Improvements in automatic telegraphy.** James Yate Johnson, 47, Lincoln-inn-fields, Middlesex. (Edward Jones Mallett, United States.)

SPECIFICATIONS PUBLISHED.

1887.

8641. **Supply of electricity for lighting, &c.** H. Edmunds. 1s. 1d.

8795. **Galvanometers.** W. E. Ayrton and J. Perry. 6d.

10,233. **Combined electrical vapour bath.** M. Maitland. 8d.

11,004. **Electrical propulsion of tramcars, &c.** M. H. Smith. 8d.

11,195. **Incandescence bodies for illuminating.** O. Imray. (Von Welsbach.) 6d.

16,473. **Electrical railway signalling device.** S. S. Bromhead. (Street.) 8d.

1888.

1932. **Electrical contact for switches.** F. H. Royce. 6d.

4673. **Dynamo electric machines, &c.** P. M. Justice. (Heisler.) 1s. 1d.

4964. **Transferring electric currents.** A. J. Boult. (Doubrava.) 6d.

NOTES.

Milan.—The local technical society intends to organise a permanent exhibition of electrical inventions for Milan.

The Clyde Defences.—It is stated that the Government have under consideration the erection of two large and powerful electric lights on the rock west of Kempock Point, Gourock.

Portugal.—According to the Lisbon papers, the Portuguese Government has given its consent to the scheme of lighting the town of Evora with electric light. The population of this town is about 25,000.

Edison's New Sensation.—Edison is credited with having another great discovery ready to startle the world. This is supposed to be the realisation of man's hitherto unsuccessful longing for aërial navigation.

Personal.—In our last issue we were a little premature in our statement relating to Mr. Reckenzaun and Messrs. Woodhouse and Rawson. The negotiations, which we understood to be completed, have since fallen through.

Burning Liquid Fuels.—A series of articles on the construction of furnaces for burning liquid fuels is being given in *The Engineer* at the present time, which may be interesting to electrical engineers, especially for working of large colonial installations.

Underground Mains at Work.—A central station on the Edison system is running at Columbus, Ohio, with 6,000 16 c.p. lamps, and also about 60 h.p. distributed for motors. The most noticeable feature is that the mains are laid on the underground system.

Gas or Electric Power.—The growth of the demand for small electro-motors in America is causing some anxiety to the gas companies. In the city of Boston it is estimated that these motors divert from the gas company the sale of 50,000,000ft. annually, an item which even a large company can ill afford to lose.

Poole.—An application has been made to the Town Council of Poole by the Electric Light Company for permission to erect iron standards in different parts of the borough for carrying electric light wires. The Council have not arrived at any decision, and the matter has been held over till next meeting.

Appeal Cases.—We are informed that instructions have been given by the Edison-Swan Company to appeal against the recent decision of Mr. Justice Kay, discussed in our issue of last week. We also understand that Messrs. Gaulard and Gibbs have determined to appeal against the decision of Mr. Justice Kekewich.

Thin Film Cut-Outs.—The Thomson-Houston Company, of U.S., have instituted proceedings against the parties operating the Heisler system of street lighting at Fishkill, N.Y., for infringement of their patent covering the film cut-outs, which can be ruptured by the high tension current in case of failure of lamps, for series incandescent lighting.

Domestic Magneto Bells.—A new system of magneto-electric bells for domestic and similar purposes has recently been designed by Mr. E. Cox Walker and Mr. A. A. Campbell Swinton, and will very shortly be introduced to public notice. The Equitable Telephone Association, of 75, Queen Victoria-street, E.C., will be the agents.

Madrid.—The Royal Opera House at Madrid is to be lighted by the Sociedad Matritense de Electrisedad. The installation will consist of 2,000 incandescent lamps, and four arc lamps for the exterior. The Government owns the theatre, and the contract is made so that after eight annual payments the installation becomes the property of the Government.

Extension of Telephone Service — The Western Counties and South Wales Telephone Company have decided to connect Bournemouth and Poole with Southampton, Portsmouth, Winchester, Gosport, Bishopstoke, and Christchurch at once. These increased facilities for inter-urban communication should lead to rapid increase of exchange subscribers.

Indian Telegraphs.—The Indo-European Government Telegraph Department has been absorbed by the Indian Government department, under Sir Albert Capel, and their offices at Parliament-street will be given up at the end of the year. Mr. Alfred Brasher, traffic manager, who has for many years translated and published the rules of the International Telegraph Congress, retires upon a pension.

Preserving Telegraph Poles.—Telegraph poles are preserved in Norway by making an augur hole about 2ft. from the ground, in which four or five ounces of sulphate of copper in coarse crystals are placed, and plugged in. The chemical is gradually absorbed by the wood, until its whole outer surface turns a greenish hue. The sulphate requires an occasional renewal, and is said to be a perfect preservative.

Valencia.—A central electric light and power station is to be erected by the proprietor of the gas works at Valencia, which will be one of the largest installations in Spain. It will consist of twelve boilers with sixteen dynamos driven direct, giving 1,200 16-c.p. lamps each. The most recent improvements will be adopted by the engineer, who has recently returned from a visit to England, France and Germany.

Use of Water-Power in the Tyrol.—The gas company at Innsbruck will shortly start a central station for the supply of 3,000 incandescent lamps. The power will be obtained from a waterfall, five miles from the town, and the current will be led by overhead wires to Zipernowski transformers situated at different parts of Innsbruck. The secondary mains will be underground. The installation is being constructed by Messrs. Ganz, of Buda-Pesth.

Wire Gauge Brushes.—A new kind of dynamo brush has been introduced by Messrs. Crompton, which is said to have proved itself very satisfactory. Wire gauge is taken, cut on the diagonal of the mesh, as it is termed "on the bias," laid together in strips and folded over once or twice, and soldered firmly down. The result is a compact, perfectly flexible brush with innumerable points of contact, which produce the nicest surface upon the commutators, wears extremely well, and reduces the sparking to an infinitesimal amount.

The Garden Roller.—At Messrs. Crompton's works, Chelmsford, is a garden-roller which is very useful in delicate testing operations. It seems an incompatible article for electrical testing, but on certain adjustments being made it was found that the spot of light from the reflecting galvanometer jumped about in a curious manner, and on search being rigorously instituted, it turned out to be the effect of

Digitized by Google

the man rolling the lawn with the iron roller. A lad is now sent out to adjust the position of this roller, so as to get the best conditions for testing.

Electric Pumps in Japan.—The Sprague Company of America has received a report from Tokio, Japan, on the operation of the electric fire-pump sent for use in the Mikado's new palace. The trials that have been made yield results exceeding the most sanguine expectations. Although the pump is on a temporary foundation and has to draw its water 12 feet, it does much more than was claimed for it. So strong is the opinion in its favour among the officials of the household, that it is probable that five or six of these machines will be placed in the palace.

Edison's American Patents.—The Edison Electric Light Company of New York, having had the case decided against them by Judge Wallace on the issue that the foreign patents had expired, and therefore the American patents are invalidated, are taking further action. They first of all deny the expiration of the foreign patents, and further deny that the expiration of a foreign patent, in point of fact, does invalidate the American patent, holding this latter point to be an absolutely impregnable position, the essence of equitable law and common sense, and will go to the Supreme Court to defend this position.

"Incandescent" Motor.—A curious anomaly appears to be cropping up in the nomenclature of motors in America. We recently saw a description of a plant where a "6h.p. incandescent motor" was mentioned. No doubt this description applied to a motor to be used on low-tension constant potential incandescent light circuits; but to call a motor "incandescent" is a peculiarity which English engineers would hardly stand. We should advise the American technical press to insist on suppressing this anomaly at once, and start off by calling their motors low-tension and high-tension motors, or L.T. and H.T. for short, or some more suitable and correct technical term.

Birmingham.—A notice has been served on the Town Clerk at Birmingham last Saturday, that it is the intention of Messrs. Chamberlain and Hookham to apply to the Board of Trade for a provisional order. The present intention is to embrace a square comprised within the following streets:—New-street, Colmore-row, Bull-street, and High-street, the current being supplied from Messrs. Chamberlain and Hookham's works in Bartholomew-street. If, as there is reason to believe will be the case, applications are received for the electric light from persons outside this radius, the area will be extended. The system to be used will supply a continuous current of electricity, and at the central station there will always be a large storage force in reserve, so that there will never be any risk of a failure in the light.

How to Improve the Telephone Service.—In New Zealand there are upwards of 2,000 telephones at work, or an average of one telephone to every 100 people in the areas served. At the same rate London would require just ten times the number of instruments at present in use, and the Sandwich Islands can beat even the New Zealand record. Now, here is an idea for the United Telephone Company, says the *Financial News*. In order to see how it is done, let Mr. Morgan, the managing director, go, say, to the Antipodes first and to Honolulu afterwards. Travelling expenses would cost the company less than his weekly journeys to Liverpool and back, which evidently lead to no improvement. While he was gone ample reforms might have a fair trial, and on his return the new ideas he had picked up might be of value.

Motor Printing in New York.—A very significant expression of opinion as to the desirability of the electric motor, says the *Electrical World*, has just been given by the well-known printing firm of Thurber, Wyland and Co., of New York. That firm learning that another large house was debating whether to put in the motor or the steam-engine, went to the trouble of writing to the firm and advising it strongly to try the Sprague motor, which they themselves found to be far better than the steam-engine for their printing office. To use their own language, "It is simpler, more efficient, needs no repairs, as there are all the time on the steam-engine, does not heat up the building, requires no engineer with a certificate, and is more economical. It does not affect the insurance, and the underwriters give permits for it. If you will investigate the experience of others who are using the motors, I think you will not consider putting in a steam-engine." This letter is signed by the chief partner, Mr. F. B. Thurber.

Drury Lane Theatre.—The annual general meeting of the proprietors of Drury Lane Theatre was held last Saturday in the saloon of the theatre. The balance was a good one, many improvements have been made, the exits have been altered, five new doors have been opened, two staircases constructed to the dressing-room, and additional doors added on the stage, and the rent had been paid to a day. But one thing was wanted, said Mr. Percy Lloyd. Electric light had been adopted at many other theatres, and why should not the committee give their attention to the question of using the light at Drury-lane. The great danger they had to guard against was fire, which, during the last few years, had caused so many fatalities. Nothing seems to have come of Mr. Percy Lloyd's suggestion at the moment, but we have little doubt that the proprietors of the "home of pantomime" have seriously thought of the question, and will shortly have to adapt themselves to the extended resources of science. The committee, as re-elected, consists of Sir George Armytage, Captain J. A. Ford, and Messrs. Edward Chitty, Edward Hicks, Jonas Levy, and Roberts Walters.

Electric Level-Crossing Signals. — An electric alarm for protecting the public using level-crossings on railways has been devised by Mr. William T. Folks, of 30, Mark-lane, London, where a large working model is to be seen. At the proper distance from the crossing a spring placed by the side of the rails is pressed by the wheels of the engine passing over it, which makes circuit and starts an electric bell placed at the crossing point; this continues to ring until the train has cleared the crossing, and has reached a point at a given distance beyond it. Here the flange of the engine-wheel presses another spring, and sends another current back to the bell which causes it to cease ringing. This simple contrivance will enable the public to be protected against the dangers of level-crossings, for the bell is set ringing before the train reaches the danger-point, and does not cease until it has well cleared it. The peculiarity of this invention is that the current is not used itself for ringing the bell, but indirectly for turning on the current which is to ring the bell. The invention is said to have received the approval of several railway engineers.

Folkestone.—At a council meeting at Folkestone, on Friday last, Mr. Logan said there was a very general feeling

Digitized by Google

in the town in favour of the electric light, and he proposed, "That a provisional agreement be entered into for three years with Messrs. Laing, Wharton, and Down, or some other firm, for lighting that part of the town which was situated within the area bounded by Sandgate-road on the south, Shorncliffe-road on the north, Earls-avenue on the west, and Cheriton-road on the east, subject to such modifications or reasonable extension as may be deemed expedient." He believed that the electric light would be found to be cheaper than gas. Mr. Vaughan wanted a larger scheme, as they required the light as much or more in the east and north of the town as in the west. But it was suggested that this could be regarded as an experiment, and if successful, the light could be extended all over the town. Alderman Sherwood objected to experiments being carried out at the public expense, and Mr. Salter wished to get further information. The resolution was carried, seven being in favour and three against. The names of the committee are: The Mayor, and Councillors Holden, Spurgen, Logan, and Thompson.

Dublin Lighting.—A special meeting of the Dublin Corporation was held yesterday week to consider and take action on the letter of the Board of Trade on the subject of electric lighting. A resolution was proposed as follows: "That the conditions contained in the letter of the Board of Trade of July 10 be accepted, and they be requested to issue a license in accordance with the conditions contained therein, but so far as the completing of the installation, at present contemplated within two and a half years, the Council desires that the clause of the license should be so framed as to leave it open to the Council to make subsequently such further extension of the system within the city as the Council may from time to time consider advantageous." Some observations were made with regard to fixing the limit of time. It was thought that a term was used in the resolution which might cause trouble in the future. The Corporation had agreed to a limit of time being fixed within which the contemplated works should be completed. Although they might be completed so far as the present works were included, if they wanted to extend or do more lighting they would have to go to the Board of Trade for another license. Whatever works or plant they erected in two and a half years they would be obliged to discontinue after that time, and a limit of time might involve them in difficulties. They had undertaken to do the electric lighting within two and a half years, but they did not know what would be necessary to complete it, and it was thought better that the Council should strike out the word "complete." The resolution was carried unanimously.

The Coming Boom.—*The Financial News*, in its issue of July 26, has a leading article upon what it terms the "Coming Electric Light Boom," in which it points out that in 1881, when it first appeared upon the scene, the electric light, like all startling novelties, ran riot in its own fascination. It sowed its wild oats with a vengeance, and has since had to do penance in sackcloth and ashes. The reaction came and everybody who could gave it a kick. Our contemporary says, "To have lived through such an ordeal is of itself ample proof of its vitality." It goes on to point out that another turn of the wheel has come round, and this time a favourable one. Our financial contemporary, considering its special experience, says: "The science of electric lighting has been greatly developed; electric engineers have accumulated practical experience, and they now have some notion of the limits of their powers; crude and visionary ideas have been weeded out, and schemes have been framed which are both scientifically and financially practicable; exact and reliable data have been obtained as to the actual cost of electric lighting under various circumstances, and on the highest authority it can be affirmed that electric lighting companies may now, with good management, do a very profitable business in any of our large towns. *Prima facie*, there is no reason why they should not. In the United States many of them are paying large dividends, and their shares are among the most solid and popular of investments."

The Paris Electrical Exhibition.—In reference to the statements made by the Lord Mayor, in his speech at the Mansion House banquet on Saturday evening last, we cannot but express surprise at the meagre manner in which English electrical industries threaten to be represented. English exhibits as a whole will be a full representation of the manufactures of the country, but those representing the industries in which we are specially interested will, as we have said, be very meagre and incomplete. Many of our largest firms are holding aloof, although we understand that appeals, both personal and otherwise, have been made to them by various representatives of the Paris Exhibition Executive Committee, and by the Society of Telegraph Engineers and Electricians. It is presumed that the feeling generally is that exhibitions do not pay. We doubt this very much: they may not pay directly, that is, few or no orders may be traced to the exhibitions themselves, and we may be told that French tariffs practically exclude many articles of English manufacture, but in cases of this kind sometimes the benefits accrue long after the effort has been made; and an exhibition in Paris does not mean an exhibition only to Frenchmen, but to the world. Those who have articles which are worthy of introduction to South Americans, Chinese, and Japanese, may all find it a convenient centre for the display of their wares at the forthcoming Paris Exhibition. We trust that even yet it is not too late to find some of our leading firms avail themselves of the saving clause by which the Lord Mayor held that, although the present space was fully appropriated, yet some extra room might be found for exhibits of a specially interesting character that might come in at the eleventh hour.

Electrolysis by Alternate Currents.—A very interesting paper has been communicated to the Académie des Sciences by MM. G. Maneuvrier and J. Chappuis with reference to the evolution of gas by means of alternate currents. When alternate currents are sent through an ordinary voltameter, with plates or large platinum wire electrodes immersed in water acidulated with pure sulphuric acid, no evolution of gas occurs, and it appears as if the acidulated water were not decomposed at all by alternate currents. For instance, with current of 4 or 5 amperes at 250 to 300 volts, which would easily light either arc or incandescent lamps, no traces of evolution of gas at the electrodes can be observed, providing the dimensions of the electrodes exceed 1 millimetre ($\frac{1}{25}$in.) diameter, and 4 or 5 centimetres (1½in. or 2in.) in length. The opinion has thus been promulgated that alternate currents do not produce electrolytic action. But the authors observe that this opinion is erroneous, and the absence of electrolytic action is only apparent. If very fine wires are substituted for large electrodes in the voltameter, the same alternate currents immediately cause an abundant discharge of gas. The authors consider that a double chemical action goes on where large electrodes are used, and indicate that, with proper

Digitized by Google

precautions, the reactions, direct and indirect, are strictly proportionate to the quantity of electricity traversing the voltameter. The total effect may be realised by utilising the double chemical effect by forming suboxides, and in this manner it would be possible to construct an electric meter for use on alternate current systems. They remark, however, that the evolution of explosive gases in this way renders the experiments exposed to continual small spontaneous explosions if certain precautions, which they intend to indicate in a further communication, are not taken.

Fuel Testing.—The anomalous position of fuel consumers in London is very apparent when we reflect that many works are driven to consume Welsh coal at eighteen shillings a ton to insure smokeless chimneys, when other and much cheaper coals having equal heating power are practically prohibited on account of their smoke-producing qualities. Mr. Lavington Fletcher showed at the Wigan trials how Lancashire boilers could be fired by hand without smoking; but the difficulty is in getting firemen sufficiently adaptable to manage the fire properly in accordance with the true principles of combustion. Mr. D. K. Clark, of 8, Buckingham-street, who acted as testing engineer to the Smoke Abatement Institution, holds that the practical solution lies in the direction of automatic action, the principle of the gazogene, for instance, in various forms, in which the solid fuel is converted into combustible gases, or that of the mechanical stoker. Experience has proved that by such means not only may smoke be prevented, but the fuel can be thoroughly and economically consumed with high evaporative efficiency. Mr. Clarke has satisfied himself from the results of long and carefully-conducted observations, that with ordinary north country slack, the cost of production of steam can be reduced by from 40 per cent. to 50 per cent. of the cost with smokeless Welsh coal; when pound for pound, the north country coal was nearly as efficient as the Welsh coal. Boiler heating by means of fuel gas is in constant use in several large installations in America, and the cost for firemen and engineers will be merely nominal in such cases, and the greatest heating effect produced. The plant required, however, is larger, and in England more attention has been paid to that of automatic stoking, and means for using a cheaper fuel such as slack. Much greater attention might with considerable financial advantage be paid to these points, especially by south country consumers, where the cost of coal is high. There are boilers at cutlery works in Sheffield which are instances of furnaces fed on a principle of this kind which enable common slack at five shillings a ton to be used, and the cost of boiler power would appear incredibly small to enforced users of the high-priced coals.

Conversazione at the Temple.—A conversazione was held yesterday week in the hall and library and adjoining apartments of the Inner Temple, and invitations were issued by the treasurer, Sir Patrick Colquhoun, Q.C., and the benchers had issued invitations for what was called a "Scientific At Home." For this occasion the beautiful hall of the Inner Templars was illuminated from outside by 22 arc lamps of 3,000 c.p., driven by a Crompton machine. A large number of electrical instruments were exhibited, and an artificial cable equal to 570 miles of submarine wire was erected. Along this messages were transmitted into the next room—representing New York, or the other side of the Atlantic generally; and the guests of the benchers had the serene felicity of watching the messages come out on slips of paper, whence they were read off by obliging manipulators. Accumulator safety lamps, batteries for driving railway carriages, old and new syphon recorders, a writing telegraph, war balloons suspended from the lofty ceiling, which at a given moment flashed forth their electrical signal to the army supposed to be encamped below, were all to be seen by the learned members of the Bar. A Wimshurst machine, labelled "dangerous,' of course was surrounded by a crowd of admiring visitants attracted by the crack of its 18in. spark. Telegraph and telephones were placed to represent London, Leeds, Aberdeen, Edinburgh, and so on, between which dispatches were sent to represent the method of communicating. The benchers had the further delectation of listening to the sweet strains of "The Flowers that bloom in the Spring" through a telephone laid on to the Savoy Theatre, and could realise that the real sounds were being transmitted when the muffled sound of applause came along the wire. A buoy lighted by electricity, "capable of remaining alight for two to four months," is well worthy the attention of naval as well as legal minds. The conversazione was eminently successful, and must be taken as a pointer to indicate how far pure modern science is invading all domains of civil and professional life. The halls and chambers in the Temple will, before long, be permanently lighted by electric light, a foretaste of which was given at the conversazione.

An Electrified River.—At Ansonia, Connecticut, they have an electric railway running, in which considerable difficulty has been always experienced with escaping currents. It affects the telephone system, causing a buzzing sound, and occasionally causes the annunciators to fall at the exchange. "Last week," says the New York *Sun*, "Mr. C. D. Warner, a local electrician, determined to test the power of the escaping current. A wire was grounded near the electric plant in Derby, no connection being made with the track, and was then run into his office in Ansonia, some three miles away. Here it was connected with the gas-pipe at his desk. The wire was cut, and a Maxim incandescent lamp was attached to the ends. The lamp was of 55 volts, and 16 c.p. The carbon at once began to glow, and as a car passed along Main-street in front of his office the lamp gave forth a clear light as strong as if on a regular light wire. As the car rolled further and further away the light grew dim, but when the grade at the foot of the Derby Hill was reached, and the motor took more of the current from the wire, the lamp again shone forth as brightly as ever. An Edison lamp was also attached, and though this required 120 volts to cause a regulation light, it showed up clearly, and gave forth light enough to read by. It remained for the ever-present small boy to discover a benefit in the escaping electricity. Not far from the street where the tracks are laid runs the Naugatuck River. In this the boys are wont to bathe. On Saturday, when the youngsters meet in swimming, they were astonished at the peculiar sensation they experienced. It was not at all disagreeable. On the contrary, it was pleasurable, though at times some of the boys would give a jump and a yell as though they had stepped on a piece of glass and cut their feet. The feeling was so pleasant that some of them remained in the water for hours, and only came out when hunger forced them to go home for supper. It is learned by experiment that the sensations were caused by the electricity, and it is proposed by the shrewd Yankees of this money-making town to lease the banks of the river and establish bathing-houses, that people may take a pleasant, invigorating electric bath at a small cost.

Testimonials.—We are indebted to the *Leamington News* for the following testimonials from persons of distinction in *re* the electric light at Birmingham:

Mr. GLADSTONE: Am so much charmed with the sweetness of your light that I shall have an installation at Hawarden, assured that it will pave the way for a *rapprochement* between your distinguished but errant brother and his natural leader, while enabling me to fell my stately oaks at night and elaborate a plan of Home Rule which any one can see through.

Lord SALISBURY: Could only have emanated from the brain of a Chamberlain—or a Salisbury. Congratulations on its splendid success. May its shadow never grow less. Am simply deterred from giving you a commission by the fear that if it were introduced I should not be able to hold any more dark *seances* in my Cabinet. Arthur, come up higher.

Lord RANDOLPH CHURCHILL: It's a light that never plays fast and loose. Therefore,

I love it—I love it, and who shall dare
To chide me for loving a light so rare!

The MAYOR: It's the best light for keeping order by.

Mr. PARNELL: Your light is the only thing I love. Forgery flies before it. My blessing follow you all the days of your life—and never overtake you as long as you live!

WILLIAM SHAKESPEARE: "Put out the lights."

Dr. THURSFIELD: "The light that never was on sea or land."

Mr. BRIGHT: "Shine on."

The TOWN CLERK: The best of lights: for it makes the dullest see my jokes.

The CHIEF CONSTABLE: Never knew such a light to run 'em in by.

The POSTMAN: It *light*-ens our labours, parcels notwithstanding.

The TOWN CRIER: 'Tis the only friend I have. It lets me cry by night as well as day.

The MASHER: 'Tis the light to show up your form.

The LADIES: 'Tis as

The light that lies
In woman's eyes.

The CHRONICLE: 'Twas good; 'tis bad.

"'Tis true, 'tis pity; pity 'tis, 'tis true."

The MEMBERS of the CLUB: Everybody's light. Overpowered by its effulgence, we have turned Joseph's face to the sunshine—we meant to say, to the electric light; and peace and harmony will reign for ever and a day.

Mr. CR-WTH-R D-VIES: Never saw such an illuminant. I can see a brief with it My dear Arthur: Let your motto be, "Brief as lightning." Exchange Nelson's telescope for Joseph's eye-glass, and I am with you light for light. Countermand the brandy and pistols.

The COOK: 'Tis "Robert's" unfailing guide to the kitchen.

Glasgow Technical College.—We have received, by courtesy of Prof. Andrew Jamieson, M.I.C.E., F.R.S.Edin., a copy of the syllabus of the day and evening classes at the Glasgow and West of England Technical College for the session 1888-89. The curriculum is a most complete one, and the utmost pains have most evidently been taken to obtain the greatest advantage in point of studying both practical as well as theoretical work for the students who join the college. Since every student is required to show proficiency in the use of ordinary workshop tools before obtaining the college diploma, a special class is held daily for students who have not previously gained experience in working in wood and metals, or in electrical instrument making. In addition to this a class is held for regular workshop students who desire to make up for any deficiency in their apprenticeship, and to get a turn at pattern-making, a department too often missed in confining the attention to drawing, fitting, and turning. A junior course of electrical engineering consists chiefly of laboratory work, with lectures and demonstrations, comprising the following: The resistance of conductors by the Wheatstone bridge, and by other methods, combined resistance of shunts and galvanometers, and of wires or electric lamps joined in "multiple arc"; the resistance of lightning conductors and of earth circuits; the percentage variation of resistance of different materials used in electrical circuits for rise or fall of temperature; the specific resistance of different materials; the internal resistance of different battery cells; the difference of potential and E.M.F. of different kinds of battery cells; the measurement of currents derived from batteries, construction and management of batteries for different purposes; the graduating of galvanometers and meters by the electrolysis of metals and by other methods; the measurement of the specific inductive capacities of different dielectrics, the construction of condensers, influence of capacity on the retardation of submarine cable and subterranean line signals, &c.; insulation resistance of different materials by aid of Sir William Thomson's galvanometer and electrometer; determination of the magnetic elements. The senior course is intended for those who intend to become electrical engineers, who will be taught how to carry out practical tests with the college engine, dynamos, and storage cells, &c., with work in the drawing office, the laboratory, such as calculating the dimensions for and designing the form of dynamos, motors, and transformers, &c.; writing out specifications for the same and for electric lighting and transmission of power installations, as well as plotting out characteristic curves. Instruction will be given in the following: Measurements of magnetic circuits and plotting out of magnetic curves, testing of dynamos working at different speeds, and plotting the characteristic curves; charging and discharging storage cells, with rules to be observed in order to prolong their life and efficiency; the working of the college condensing and non-condensing engine, taking of indicator diagrams, and making brake and other tests; ascertaining the efficiency of steam-engine and dynamo, separately and as a whole; photometric tests of arc and incandescent lamps; testing transformers and finding their efficiency by the calorimeter and by other methods; electro-plating, electrotyping, and the deposition of metals generally by electricity; electric welding on a small scale; drawing office work; visiting electrical installations, and writing out descriptions of the same with sketches. The college engine is a splendid experimental engine, which has been purchased for the college, costing over £300. A special feature of the teaching in connection with indicator diagrams is the selection of some of the best students in each section to take indicator diagrams and brake horse-power tests of the college engine, while the others watch the operations and take notes. The whole class then have to work out the horse-powers and find the efficiency of the engine. Courses on magnetism, on static electricity, and for electrical testing and research are also arranged. Courses of lectures on electrical engineering by Prof. Jamieson, assisted by Mr. James Livingston, A.S.T.E., are arranged with special regard to the departments of telegraphy, telephony, electric lighting, and electric transmission of power. Other courses on mechanical engineering, and on steam and steam-engines, both theoretical and practical, complete the syllabus of what must be termed a most serviceable and comprehensive course.

NOTES ON DYNAMO CONSTRUCTION.

BY SYDNEY F. WALKER.

(Continued from page 52.)

The drum armature has many considerable advantages. Our American friends early discovered this fact. As they put it, the dynamo that was constructed as though it was wholly of iron—field-magnets, armature and pole-pieces being in one mass, and then had a cylindrical piece cut out where the poles are situated, and wire wound in the cut—formed a remarkably efficient machine. Years ago, too, at the Trinity House trials between the Gramme and Siemen's machines, the latter had the decided advantage, and we now know that it was on account of the very much lower resistance of the magnetic circuit, owing to the greater mass of iron in the core of the armature, its length, and the form of the field-magnets. By properly constructing the armature, however, the ring and disc pattern can be made to contain very nearly as much iron as the drum pattern; not quite, of course, on account of the necessity for providing for the driving arrangements, and the internal copper wires. The Siemens' has also a decided advantage in the matter of the electrical resistance of the bobbin. In the ring pattern only half the wire is doing work, while in the drum pattern all the wire is, except that crossing the ends, which, in a bobbin whose length greatly exceeds its diameter, is not much. So that there is a smaller charge on the total E.M.F. generated for the resistance of the armature, adding, of course, to the efficiency of the machine. Against this there are the serious practical difficulties, that the armature is more difficult to wind, especially if there are to be many sections; that the coils overlap one another at the ends, so that two wires at highly differing potentials may be in close contact, and a spark caused by a sudden change in the outer circuit may break down the insulation and burn the coils. The Siemens' winding has also the disadvantage that it necessitates double the number of layers. You cannot wind a drum armature so that the coils are in series all round the bobbin without going twice round. Taking, say, for simplicity, eight coils and eight sections of the commutator with Gramme winding, you would divide your periphery into eight sections and wind a coil in each. With the Siemens', however, you divide your periphery as before; but when you have wound four coils, or half the total number, whatever that may be, you have filled up the surface of the bobbin, and to get in your other four you have to go round again; you cannot get over the difficulty by winding every other coil from opposite sides, as you will then have, side by side, wires in which the full difference of potential of the machine exists. In any case, as before explained, you have this with the wires crossing the ends. The necessity of having two layers of wire also leads to another serious drawback—viz., the core is thrown further back from the pole-pieces. The electrical resistance is not affected as the same number of turns being required, your wires may be of double the sectional area, but this again tends to increase the space occupied by the copper wire, and to throw the core still further back. The increase of magnetic resistance, due to increased space occupied by air and copper wire, is partly neutralised by the decreased magnetic resistance of the core itself, but not all, and a consideration of the above will show that the claims of Gramme and Siemen to superiority under modern conditions are by no means easy to adjudicate on. In the early days, when both types had a great many layers of wire, the Siemens' had undoubtedly the advantage. At the present time the question is one which can only be answered by actual figures in each individual case. Another point that deserves consideration is, that in order to re-wind a coil of a drum-armature when burnt, it is necessary, if it happens to be an underneath coil, to strip the whole armature. It is as well to point out here, however, that shunt-wound machines can only burn their armatures through defects in the armature itself. No lowering the resistance of the external circuit will do it, as the effect of the latter is to lower the E.M.F., and when the external resistance = 0, the E.M.F. = 0 also. The drum armature has also the advantage, that all the wire is exposed to the air, though, again, the wires crossing the ends have not so much ventilation as some modern type of Gramme armatures. Ring armatures have been adopted more generally in England no doubt on account of the patent rights having been freed at an earlier date, but they have undeniable advantages, among which simplicity of winding is by no means to be despised, and the fact that any coil can be replaced without stripping the armature. Disc armatures have only been adopted in a few special cases, such as the Brush, the Schuckert, the Victoria, and the Gülcher. There are several serious drawbacks to this form of armature. One is the difficulty of laminating the core in the direction of the lines of force, and at the same time providing for efficient driving. Where, as in the Brush machine, the lines of force all pass through the ring parallel with the axis of rotation; the desired lamination may be effected by constructing the core of ribbon of a width equal to that of the core itself, and there is not much difficulty in holding this mechanically so as to drive properly. But where, as in the "Victoria," the "Gülcher," and others, the pole-pieces are in the form of a shoe, enclosing the armature on three sides—that is, its periphery and part of its two vertical faces—then, as the lines of force must enter from the periphery as well as from the sides, only lamination in every direction, such as a wire core gives will meet the case. Here comes in the difficulty of driving; as, in order to preserve the form of a disc of wire, it will be necessary for it to be held in forks, or some equivalent appliance for a considerable portion of its radial depth, and these forks will not only take up some of the space that would be occupied by the copper wire, but will also necessitate the core being further from the pole-pieces on its vertical faces. The writer believes that no core made wholly of wire has yet been used for disc armatures. Mr. Brush has, as usual, got over the difficulty in a novel and ingenious manner, though his recent improvements show the earlier machines to have been exceedingly wasteful in this matter. In fact, it is no uncommon thing to find the iron core of an old type "Brush" armature hot, while the wires on it remains cool. Dr. Hopkinson has shown that the loss due to Foucault currents in the "Brush" armature was not so great as it might have been, if, instead of the disc being an iron casting, it had been made of wrought iron; owing to the fact that cast iron has a considerably higher electrical resistance than wrought iron. It would be interesting to know whether the gain from the increased electrical resistance is equal to the loss due to the increased magnetic resistance, or *vice versâ*. Other makers of disc armatures appear to have adopted a sort of compound core, built up with a small cast disc for a foundation, and then ribbon, which latter has been slotted radially, in order to provide what may be termed breathing spaces for the air current to pass through, and in order to lessen the Foucault currents. Another plan, adopted by the Gülcher Co. in some of their machines, is to have a central disc of wood, with projecting wood teeth on its periphery. On each vertical face of the wood disc are screwed thin iron discs, and the copper wire is wound over all in the space formed between the wood teeth. The driving arrangement on this armature smacks very much of the old wood hub. It consists of two flanged brass hubs, entering the armature from opposite sides and held together by bolts and nuts, the inner diameter of the armature being formed V shaped, to take the grip of the hubs, and protected by leather. The arrangement seems a remarkably good one mechanically, but it evidently has a high magnetic resistance. The disc pattern of armature gives one very great advantage over other forms, at any rate as generally constructed. It allows a free circulation of air over a large portion of its surface, so that for given work, other things being the same, a smaller gauge of wire should be permissible. Further, there is very little fear of the periphery of the disc armature rubbing on the pole-pieces; but there is great fear of its vertical faces doing so, should there be any end play. For this reason, the spindle of disc dynamos have to be provided with some special arrangement, such as grooves running over corrugations in the bearings, or other special fittings, to prevent motion of translation and consequent rubbing. The Pacinotti form of armature, in which the core is formed of a series of toothed iron wheels insulated from each other and held together on the spindle, the

Digitized by Google

wire being wound in the grooves formed by the teeth, has, in the writer's opinion, very little to recommend it from a practical point of view. In the first place, the machinery required to work these plates is very much heavier and more expensive than that used in forming wire cores. It is also far more difficult to ensure that you have not left some little point or burr sticking up that will in time work through the insulation, and it is far more difficult and more expensive to wind than either the Gramme, Siemens, or disc patterns. It has already been mentioned that some portion, at least, of the advantage due to decreased magnetic resistance is sacrificed, owing to the heating of the pole-pieces; and it is the writer's opinion that there is absolutely no gain in the output of a machine using a Pacinotti armature over one using either a drum or ordinary ring core. To put the case in another form: If a dynamo machine be constructed with field-magnets of a certain size, and two or more armatures be constructed for it, one of which shall be a Pacinotti and the other either a Siemens or an ordinary Gramme, using the same weight and length of copper wire for both, it will be found that the ordinary Gramme would be equal, if not superior, to the Pacinotti. As Prof. Silvanus Thompson and Mr. Esson have both expressed themselves to the contrary, and the latter has maintained the courage of his opinions by constructing the dynamos of his firm on the Pacinotti plan, it may be well if the writer's reasons for the above opinion be stated. Both Professor S. Thompson and Mr. Esson's opinions have —the writer believes—been derived from experiments that were misleading. In each experiment only a portion of the surface of an armature was wound, vacant spaces being left. In one case these spaces were filled in with iron, and in the other case two rings were made, one with teeth and the other without. In each case the surface of the core on the inner side of the outer copper wire was at the same distance from the pole-piece, so that the effect of using teeth in one case and fixing iron in the vacant spaces in the other was to directly reduce the average magnetic resistance. It is evident, however, that whatever the portion of the periphery occupied by the teeth may have been, the magnetic resistance could have been reduced equally as well by bringing the whole surface of the core nearer the pole-pieces, and reducing the layers of wire, but maintaining the same number of turns. Take, for instance, the case of an armature, half of whose surface is occupied by these teeth, and having four layers of wire. If the teeth be cut away, and the diameter of the core increased by half the depth of the teeth, the magnetic resistance would be the same or less, and the winding space greater, as the two layers of wire would be wound on a larger circumference, and there would be no space taken up in insulating the teeth themselves, while the winding would be easier. In addition to this, the channels in which the wires lie do not allow of ventilation, and, in fact, tend to lower the possible density of the current as they become very hot. The armature has, however, one advantage: the projecting teeth protect the wire from rubbing on the poles. The new armature of Mr. Chas. Lever, in which a portion of the Pacinotti projections are carried into grooves in the pole-piece, form a striking instance of ingenuity in reducing the resistance of the magnetic circuit; but in the writer's opinion it is doubtful whether the gain will not be a minus quantity. The construction appears to him to be open to all the faults of the Pacinotti, and to be more expensive.

(To be continued.)

ELECTRICAL ENGINEERS.

I.—MESSRS. R. E. CROMPTON AND CO.

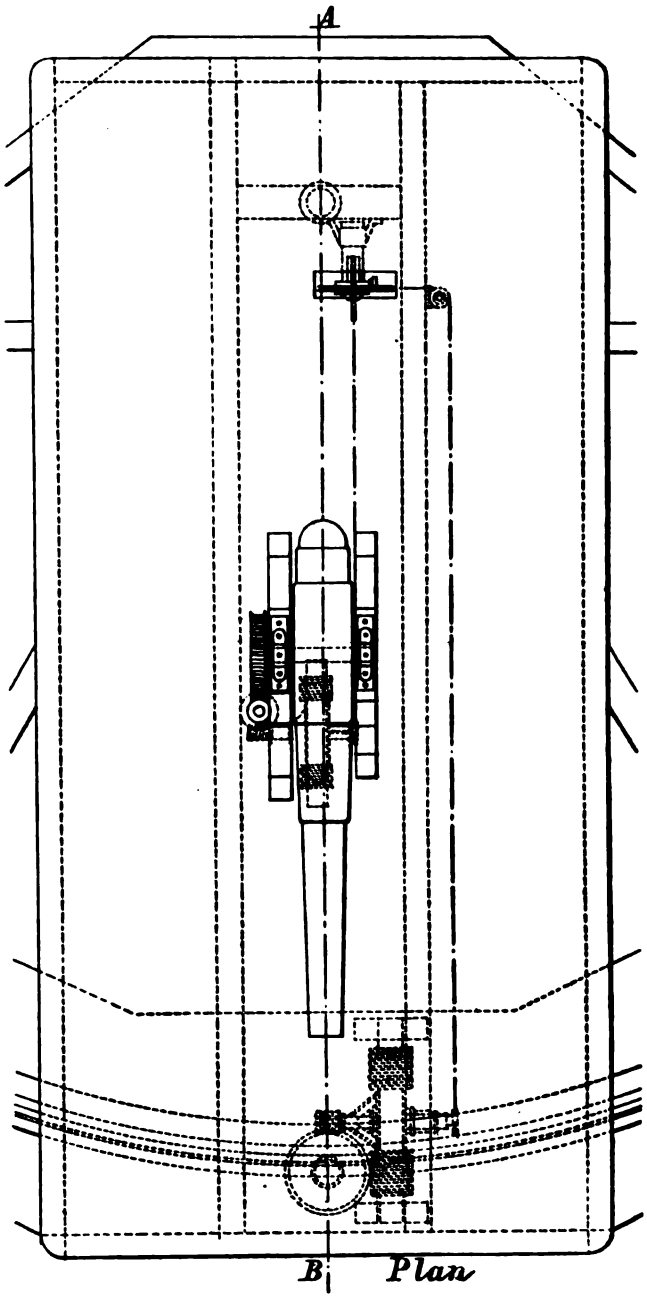
(Continued from page 58.)

Electrical Gun-Training Gear and Electric Crane.

At the works of Messrs. R. E. Crompton and Co., Chelmsford, as mentioned in our description of their works last week, some special pieces of electrical apparatus were shown, and experiments were made to show the capabilities of the electro-motor applied to certain engineering problems. One of these was a gun-training gear, mounted upon a carriage, a model of the apparatus applied to a 38-ton gun at Woolwich, and the second an electrical crane to be used for unloading timber, &c., for the roof of a warehouse near a wharf.

Gun-Training Gear.

The first illustration shows the apparatus on plan. Two electro-motors are fixed beneath the platform, one to effect the action of rotating the platform through a portion of a circle, the second to effect the raising or depressing of the gun itself. The gun is mounted upon a platform having a certain radial revolution, geared to a quarter circle of rail, cogged on its side, to a small tooth-wheel, which itself is rotated by a worm gearing attached directly to the motor.



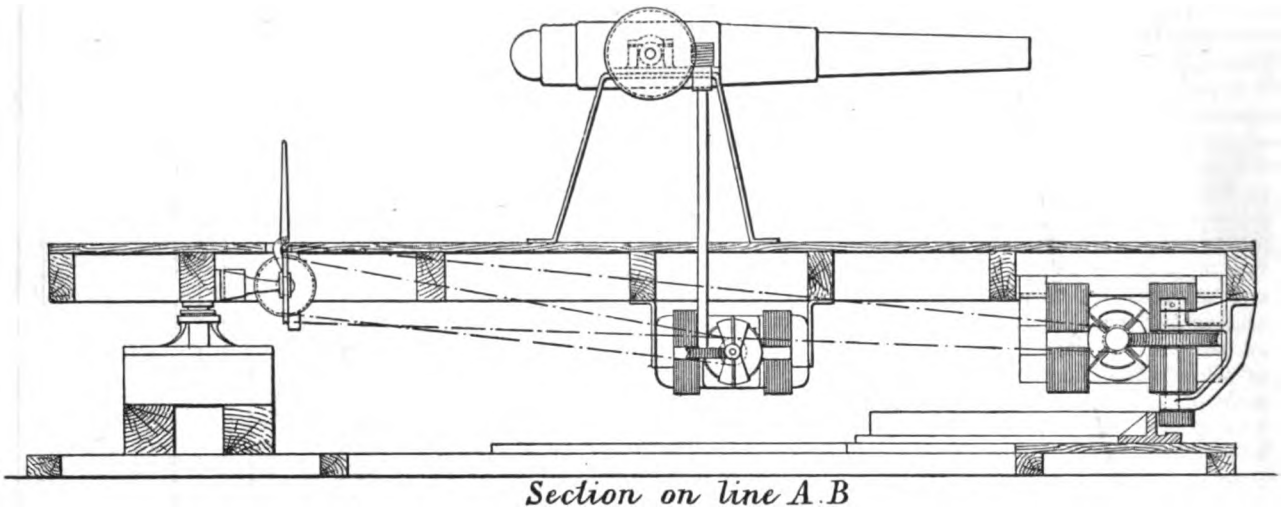
The gun itself has a tooth-wheel connected to its axle, which is likewise geared to a worm-gearing which can be rotated by means of the second electro-motor.

The regulation of these motors is effected, not in the usual manner with resistances or other apparatus, but by the shifting of the brushes, the motor being specially wound, so that it can be started, stopped, reversed, or run at any desired speed, merely by adjusting the position of the brushes upon the commutator. This being so, a simple movement to the right or left of a handle connected to a wheel, over which passes a chain to pull the brushes backward or forward, will be all that is necessary to regulate the motor. A simple and ingenious contrivance is used to effect the necessary movements of the brushes of both motors with one single handle, so that the rotation of the carriage and the elevation or depression of

Digitized by Google

the gun are accomplished with the greatest ease, either together or separately, and moving in either direction as desired.

This is accomplished by the action of two wheels mounted together at right angles to each other, so that their various movements can go on at the same time, one wheel moving (so to speak) to the east and west, and the other north and south. The movement of these two wheels is effected by a lever with a peculiar crook in its end, seen in the illustration. On moving this lever forward or backward one set of brushes is moved, and the revolution of the platform is accomplished. On moving the lever in the direction of right and left the other set of brushes is moved, and the gun is depressed or raised as desired. These two motions can go on simultaneously in either direction, or independently of each other. The gun can be trained through a full horizontal angle of 80deg. in about 25 seconds, and elevated and depressed through the full range in 12 seconds.



Section on line A B

The second illustration shows the apparatus in side elevation and section.

Electrical Crane.

An application of the same type of motor to the construction of a crane was also shown. The motor is geared to a main-shaft on the platform of the crane. This is kept rotating at a constant speed while the crane is in action, and friction gear is adapted by means of bevel wheels, so that the three motions of travelling, steering, and hoisting can be separately or simultaneously operated from the one motor. The crane will hoist one ton 80 feet in one minnte. The speed of the motor is constant, and the E.M.F. is also kept constant; the current varies with the power required from about 10 to 45 amperes with a pressure of 95 volts.

THE RELATIVE MERITS OF IRON AND LEAD COVERING FOR CABLES.

BY DAVID BROOKS.

Among the advantages of iron over lead, beside cheapness and greater strength, wrought iron is free from pores. In coiling and uncoiling lead you are liable to open pores. As lead tubing is coiled, the outer surface of the tube forming the circle is elongated and the inner surface compressed, and this condition is produced by the comparatively rigid nature of the cable or conductors inside. If the insulation consists of paraffin, which is all broken up by the coiling, the moisture goes directly to the conductors. If it goes to the mixture of resin and resin oil it stops there, provided it does not reach the textile covering. In that case it finally penetrates the covering and reduces the insulation. Wire after wire will fail. Wrought-iron pipe is rigid and has no pores, that being proved under a pressure of from one thousand to two thousand pounds to the square inch. The socket-joints are rendered moisture-proof by the use of a cement of white lead and linseed oil; but supposing the socket-joints are not perfectly moisture-proof, the insulating material is poured directly into the socket at a temperature of 400 degrees Fahr. and fills all apertures. On cooling, it will remain and prevent all ingress of moisture. When lead is drawn over a cable the textile covering comes directly in contact with the lead, and the pores opened in the lead admit moisture to the textile covering. Thereby insulation fails. In iron pipe the position of the cable is shown by two circles, the outer circle representing the pipe, the inner circle that of the cable. The space between the two circles is filled with the insulating mixture, which is heavier than water and does not crack or check, being semi-fluid at a temperature below freezing. It will be seen that the chance of moisture reaching the cable is exceedingly remote. Lead-encased cables are very little used in this country except for telephonic purposes, and then for short distances, seldom over a mile. Telephones can be worked for that distance with very low insulation. To remedy the difficulty—porosity of the lead—they are sometimes laid in a trough and covered with pitch. Felten and Guilleaume cover the cable with a braid saturated with bitumen. Berthoud-Borel draw on one covering of lead and cover that with an insulating material, and over that draw a second lead covering.

As to comparative cost, a lead cable 1in. inside diameter, of the weight usually used in this country, costs 12 cents per foot or upwards. An iron pipe, lap-welded, 2½in. diameter, suitable for the purpose, can be had at 12 cents per foot. The capacity of the iron pipe is over six times that of the lead, and it can be made to contain six times as many conductors with the same amount of covering or insulation, or we can give the conductors six times the insulation and less than one-sixth the electrostatic capacity. It is a very easy matter to make an electric light conductor show an insulation of from five thousand to twenty thousand megohms per mile and at trifling expense as compared with ordinary modes of insulation.

The cable that I laid a year ago of this new system shows higher insulation at this time than when first laid. I can say at even temperature it is more than twice as high. It does not cost over one-quarter that of the cheapest of other systems. The insulation is protected by wrought iron. The outer surface of the pipe is protected from oxidation by a coating of pitch or asphalte.

The method of laying it is so simple that any person can do it without previous experience, it being only necessary to strictly follow the printed directions.—*Electrical World.*

A TABLE OF INCANDESCENT LAMP LEADS.

The accompanying table is based on Matthiessen's determination that the resistance between opposite faces of a centimetre cube of pure annealed copper at 0 deg. C. is 1,598 legal microhms; it is calculated for 98 per cent. copper at 75 deg. F., from the formula:

$$d^2 = \frac{20\,D\,C}{P}$$

Where d = diameter of wire in mils.
„ D = distance of lamps in feet.
„ C = total current in legal amperes.
„ P = allowable fall of potential in legal volts.

To Use The Table.

Find the required current in the first column marked "amperes," and follow the horizontal line to its intersection with the column giving the required distance of the lamps, and divide the number at this intersection, under the head of "circular mils.," by the allowable loss of potential expressed in volts. The quotient will be the d^2 of the required wire, and the corresponding number of the wire, in any gauge, may be found by reference to the ordinary wire gauge tables

For all round numbers from 1 to 1,000 amperes, and 10 to 10,000 feet, at 1 per cent drop, the size of the wire, in American gauge, is given directly by the table. Where greater accuracy is required, the values of d^2 for intermediate currents and distances are separately determined, as above, and then added together, their sum being the d^2 of the required wire.

Examples.

(1). It is required to find the size of wire which will convey current to 200 100 volt ½ ampere lamps, located at a distance of 500 feet from the source of current, at 5 per cent. loss of potential.

Method.

Two hundred lamps of ½ ampere each will require 100 amperes, and 5 per cent. of 100 volts makes the allowable loss of potential five volts. At the intersection of the 100 ampere line, and 500 feet column, "circ. mils." = 1,000,000.

$$\therefore d^2 = \frac{1{,}000{,}000}{5} = 200{,}000 \text{ cir. mils.} = \text{No. } 000 + 5 \text{ B \& S}$$

(2.) It is required to find the size of wire which will convey current to 50 lamps of 50 volts and 1 ampere each, for 150ft., at 2 per cent. drop.

Method.

Fifty lamps of 1 ampere each will require 50 amperes, and 2 per cent. of fifty volts makes the allowable drop one volt.

50 amperes at 100ft. gives circ. mils. = 100,000.
50 „ „ 50ft. „ „ „ = 50,000.
$\therefore d^2$ = 100,000 + 50,000 = 150,000 circ. mils. = No. 000 + No. 8 B. & S. gauge.

FACETIÆ.

Dreamt the Shock.—E. P. Roberts, of Cheyenne, Wyoming, got his boots wet one night, and touching a bare place on the Brush dynamo, got a shock in his arm that sent it out with a jerk like a ten-ton gun, almost dislocating it. That night he dreamt he had taken another shock, the effect on the muscles was the same, and his bedfellow got a bang which nearly knocked him out of bed, and awakened both of them.

Not that Kind of Switch.—We cut the following delicious note from a contemporary newspaper, where it is given as an item of news, and the remark is made in all good faith. "A man in the North of England has just had a patent granted him for an electric switch. The particulars are not given, but it looks as if the future of the small boy was very discouraging." The editor has evidently a more vivid and *tender* recollection of boyhood's days than knowledge of science in his manhood's prime.

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, ESQ., *President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of* W. H. WOLLASTON, M.D., F.R.S., *and on April 20th we gave that of* SIR HUMPHRY DAVY, F.R.S., *whose fame as an electrician is still more prominent than that of* WOLLASTON. *Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of* PROF. D. E. HUGHES, F.R.S.

A COMMON PLATFORM.

The long and arduous labours that some individual members of the electrical engineering profession have undergone to obtain a business-like modification of the Act of 1882, have thoroughly imbued them with the idea that combination is necessary. The interpretation of the combination we refer to is one that has for its object the general business welfare of the profession, and not one that is instituted solely for the purpose of obtaining a virtual monopoly under the guise of free competition. Common interests require a common platform and collective action. Hitherto this common action has been obtained with great labour and difficulty. Probably no one outside the Brush Company's office, for example, will ever know the difficulties that have been encountered, and the labour gone through to overcome these difficulties, in order to obtain the modification of the Act above referred to. As each particular crisis has arisen in the development of the industry, it has become necessary for some one of the more prominent firms to take the matter in hand, feel, so to speak, the pulse of the profession, and obtain conjoint action to carry out the particular object in view. Especial difficulties have been experienced in all that pertains to parliamentary action, and thus when once the question of combination had been broached it commended itself to most of us; but, till quite recently, the best means of obtaining what was wanted was not self-evident. The history of the movement, so far as the technical journals is concerned, should be made quite clear. The original suggestion came from our contemporary, *The Electrical Review*. The suggestion, like many another good thing, was put foward too early, and found at the moment little support. After a time, the matter was brought forward again by the present writer, and subsequently *Electrical Plant* suggested the formation of an electrical branch in connection with the London Chamber of Commerce. This plan seems to have been thought the most feasible of all, and at the invitation of Mr. R. E. Crompton a large body of representative members of the profession met last Friday at the Holborn Restaurant, to meet the Secretary of the London Chamber of Commerce, and to discuss with him the best mode of procedure in order to obtain what is required. According to the explanations given at this meeting, in order to become a member of the Chamber of Commerce, the candidate must be nominated by a member, pay an entrance fee of two guineas, and an annual subscription of one guinea. If a sufficient number of members of any particular trade is enrolled, they can form a sub-section, governed more or less by their own bye-laws; of course, all through, being subject to the general laws of the Chamber and to the Central Council. The routine business of the section—as a section—is carried on by its own elected committee and officers.

Digitized by Google

Members are not restricted to London, nor are the members of any one section restricted to the meetings of that section only, but can, on application, visit the meetings of any other section in whose proceedings they are interested. Here then, we find a fully organised society to hand, which offers all the advantages we require, and at less expense gives far greater facilities than could possibly be given by a newly formed and organised society. The special work of the section is the welfare of the trade it represents, while, as is easily seen, the collective work of the Chamber is the welfare of trade generally. It must be noticed that the organisation offered and desired partakes of nothing of the scientific character. We get enough, and perhaps too much, science at the British Association, the Physical Society, and the Society of Telegraph Engineers. The proposed section of the Chamber of Commerce will discuss the hindrances to trade, and the remedies to these hindrances; will be able to act quickly and effectively in future legislation, and especially will take cognisance of the duties collected by foreign nations, or by our own Government, upon the manufactured or raw material forming the staple of the trade. There are scores of questions which cannot be indicated here, but all of which influence the whole industry that can and will come under review. Sufficient arguments, however, have long ago been advanced to prove the necessity for such combination, and we have now endeavoured to emphasise and explain that a good opportunity offers for at once getting to work. The cry at the meeting was against further procrastination, and it is to be hoped that everyone will immediately join so that the committee may be elected if the number joining be too great for the whole to act as a committee, and thus the section get into working order. There is a pressing question that merits the collective wisdom of the trade. Rumours are rife that some enterprising firms from across the Atlantic mean to make a landing upon our shores, and hope to get a good deal of the trade of the immediate future. If these firms obtain a footing here and are successful in their competition, it will show that something is wrong somewhere when those on the spot, possessing equal facilities, cannot command the market. At the present moment no doubt such remarks may savour of selfishness; but we ask, what is is the use of trade combination if it is not to help to keep our home trade, and to get as much export trade as the conditions of competition will allow? The suggested combination, however, presents nothing but good features, and deserves the hearty support of all engaged in the industry. The time, when it is proposed, is most opportune, happening just when there seems to be a decided revival in the purely business prospects, and, should the promise be fulfilled, there will constantly arise questions of common interest which could beneficially be discussed and decided by such a section of the Chamber of Commerce.

STILL AN INFANT.

Elsewhere we give a report of the meeting of the Bath local authorities to consider the question of introducing the electric light into their city. It will be noticed that one of the arguments used against the introduction of the light is, "that it is now in its infancy." This argument is used by men all over the country, and we think the time has come when every opportunity should be taken by those interested in the progress of the light to combat the fallacies included in the argument. The men who talk in this fashion do not know what they are talking about. They get hold of a catch phrase which sounds well and means anything, without themselves attaching any specific meaning to it. Did the dye works reject the use of aniline dyes because they were recent discoveries of Perkins?" Did they not rather test them to see if they were as good as they were said to be, and finding them so continued to use and extend the use? In the early days of steam locomotion, if the world had waited for perfection the world would have been waiting still. No doubt objections were taken because of the infancy of the system, the desire to get rid of steam and smoke. The opponents wanted noiseless aerial carriages, always available, and, of course, costless. Now, we do not deny that improvements can and will be made in electric light apparatus, but from many points of view the possible improvements do not mean much. If we consider the generator, that is the dynamo machine, a large number of makers will even now guarantee a commercial efficiency approaching to ninety per cent. In other words, a hundred mechanical horse-power put into the dynamo results in 90 more or less e.h.p. given out by the dynamo. It is impossible to conceive a machine of this kind in which there shall be absolutely no loss, and if we are now in the infant stage we hardly see how the adult stage can be so very much better. We may take it for granted, then, that waiting will neither give us better engines nor better dynamos. The Bath authorities were discussing an overhead system of distribution and lighting by means of arc lamps. These are the simplest and cheapest forms of distribution and obtaining light that are known, and it is difficult to see where material improvements in these directions are to come in; at any rate, waiting for the adult stage to be reached, if it is not yet reached, can only result in reducing the cost fractionally. Then there is the old argument, Oh, you must not have the electric light, because if you touch the wires it certainly provides work for the coroner. Is it any more necessary to touch wires than it is to hunt for a gas escape with a lighted candle? Besides

Digitized by Google

the wires should be out of reach and could not possibly be touched accidentally. These are the terms in which those who oppose the introduction of the electric light are apt to speak. Fortunately, in the case of Bath such counsels do not prevail, but there are other places where opposition carries the day and succeeds by means of these arguments which, when examined, possess neither rhyme nor reason. We are glad to be able to state from a telegram just received that the supporters of the electric light scheme for Bath have succeeded in their purpose, and that the tender of Mr. Massingham has been accepted. The system to be adopted is the Thomson-Houston, which has proved so satisfactory at Taunton. It is to be hoped that a little more experience with the light will cause a change of opinion as to its infancy. Opposition on the ground of economy can be understood, and so far as street lighting with arc lights and overhead distribution is concerned can easily be controverted. When our streets are properly lighted at night, someone will wonder why semi-darkness was so long tolerated. More and better light saves both time and money. More work can be done in a given time with a good light, locomotion is easier and quicker, so that the saving indirectly, even if there is none directly, can hardly be of small proportions. Yes, the infancy stage has passed; the light is scientifically and commercially successful, and now that certain legislative disabilities have been removed, it remains only to give confidence in its capabilities to the various authorities throughout the country in order to obtain a large increase in its use.

CORRESPONDENCE.

VALVE-GEAR TO COMPOUND ENGINES.

To the Editor of The Electrical Engineer.

Sir,—With reference to your issue of the 20th instant (page 52), which contains a notice and illustration of our 12-h.p. Robey engine exhibited at the Nottingham Royal Show, we beg to point out that there is a slight error in your description, wherein you say, "though usually, we believe, they are fitted with the Proëll gear."

As a matter of fact, our compound Robey engines are all fitted with link expansion gear, controlled by Richardson's patent spring governor.

We have some time ceased manufacturing the Proëll gear, except when specially ordered; our new trip-gear, as exhibited at the Royal Show, possessing many advantages over the former, and lending itself better to be controlled by electricity, for which purpose it was specially designed.—Yours, &c., Robey and Co.

HOT BEARINGS.

To the Editor of The Electrical Engineer.

Sir,—Referring to Mr. Broadbent's (?) letter in your last issue may I ask whether bearings of either fast or slow engines, &c., of any sort get heated? If not, then there is no necessity for a detector. But if, as I have good reason to believe, hot bearings are a frequent source of trouble, there is ample demand for simple apparatus which gives timely warning (without requiring attention) as supplied by Messrs. Elliott Bros.

True, hot bearings, like many other things, *ought* not to occur, but they do; and although Mr. Broadbent may not allow any under his charge, yet all engineers are not so careful.—Yours, &c., W. T. W. Thackeray.

Aldeburgh, July 25.

RE THE ELECTRIC INCANDESCENT LIGHT PATENT CASE.

To the Editor of The Electrical Engineer.

Sir,—Referring to your article of the 20th inst., let me ask you and your readers whether it is not quite sufficient to prove "commercial success" to show success on even the smallest scale—that is, that the patent was calculated to benefit even the smallest section of the public. For instance; if the patentees, Messrs. Swan and Edison, can show that a few noblemen and others possessing valuable libraries or picture galleries would have been benefited at even a considerable outlay by adopting the electric light in place of gas, which produces such irremediable injury to books and paintings, I ask you whether the claim that the lamp "could have become commercially successful" would not have been sustained by the facts?—Yours, &c.,

24th July, 1888. H. A. K.

TRAMWAY WORK.

A correspondent writes, and among other things desires information upon the following points:

First, the exact data as to when the first electric car was run in England or on the continent by the aid of storage batteries.

Secondly, how the storage batteries were inserted in the car, whether through the outside panels of the car or through the end thereof?

THE LUGO MOTOR.

In discussing the various methods by which motion can be obtained with combinations of magnets and wires carrying currents, Faraday, in his "Researches," remarks that "the motion between two poles and two dissimilar wires (helices) is an instance where several powers combine to produce an effect." It is upon this principle that Dr. Orazio Lugo, of New York, has constructed an electric motor which embodies a novel principle which seems destined to a wide application.

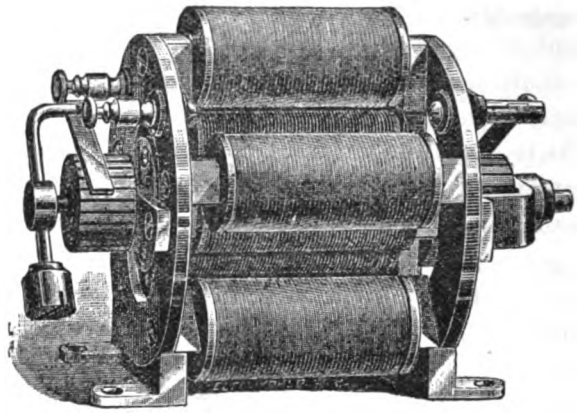

Fig. 1.—The Lugo Motor.

The new motor of Dr. Lugo is constructed so as to utilise the maximum effects found in placing moving solenoids in proximity to fixed solenoids in such relation that, as the armature coils move, a maximum number of lines of magnetic forces is cut in the passage of each armature bobbin past each field-magnet bobbin, and these effects are made successive, so that there is a continued application of such successive effects. And, in addition to utilising these effects, due to a specified relation of the solenoids themselves, the combined effects of these solenoids and their cores also are employed.

By creating such successive magnetic circuits through successive armature and field bobbins in pairs until the series has been gone through once in each complete revolution of the armature, each armature bobbin being in circuit

Digitized by Google

at least once in a complete revolution with each field-magnet bobbin, and all of the bobbins, both of the armature and field-magnets, being allowed to rest magnetically by being cut out of circuit during a fraction of each revolution of the armature, the evils effects of Foucault currents are said to be largely avoided.

The motor, which is of very simple construction, is shown in perspective in Fig. 1 and in cross-section in Fig. 2. As will be seen, it consists of a series of bobbins arranged in a circle to the number of five, and within which there revolve four similar bobbins attached to the shaft of the motor. All these bobbins are provided with cores and short pole-pieces, which revolve in close proximity to each other.

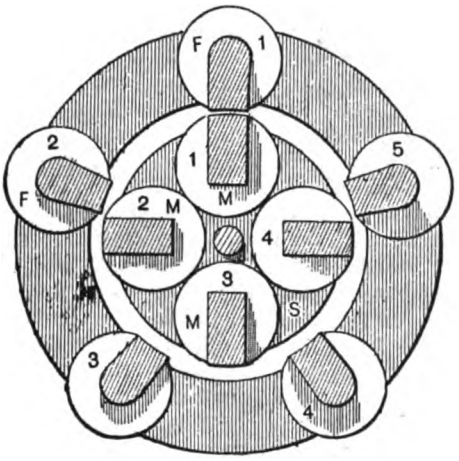

FIG. 2.

The revolving armature coils are connected to a commutator fixed to the shaft, upon which bears a stationary brush, B^1, shown in the end view, Fig. 3. The connections of the individual armature bobbins to the commutator are seen in Fig. 4, which shows also the cross-connection between the commutator strips. The other side of the armature shaft carries a revolving brush, which bears against a fixed commutator to which the field-bobbins are connected. Finally, Fig. 5 shows the circuits diagramatically, with the bobbins laid side by side, and showing the manner of their connection one with the other.

It will now be readily understood that if a current be passed through the armature and field-bobbins M^2, F^2, the pole-pieces are in such a position as to cause M^2 to be attracted to F^2 and cause rotation in the direction of the

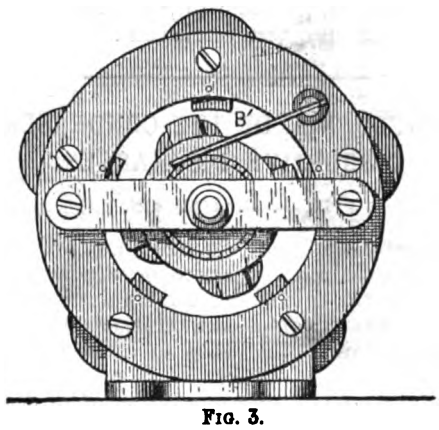

FIG. 3.

hands of a watch. This attraction continues until the pole-pieces M^2, F^2 have arrived exactly opposite each other, or in the position in which M^1, F^1 is shown. At this instant, however, the current is shifted to the bobbins M^3, F^3, which will then have arrived at the relative position formerly existing between M^2 and F^2, and the magnets act in succession, as follows: M^4, F^4; M^1, F^5; M^2, F^1; M^3, F^2; M , F^3; M^1, F^4; M^2, F^5; M^3, F^1; M^4, F^2; M^1, F^3; M^2, F^4; M^3, F^5; M^4, F^1; M^1, F^2; M^2, F^3; M^3, F^4; M^4, F^5, and back to the starting point M^1, F^1.

Thus, in every revolution of the armature shaft, each armature coil is placed in circuit with each field coil; and, there being four of one and five of the other, it follows that there are twenty successive pulls at as many radial positions of the shaft, each pair of coils being in circuit successively only during one-twentieth of a revolution of the shaft. It will be noticed that the stationary commutator is divided into four groups of segments, five in each group, while the rotating armature is divided into five groups, each of which has four segments. An examination of the circuit will show the commutation of the four armatures and five field bobbins. It is evident, however, that any desired number of field and armature bobbins may be combined, it being only necessary to so commutate the circuits as to make the effect of the magnetic pull on the bobbins successive in its action.

With a motor constructed in the manner just described, Dr. Lugo claims to utilise the power due to the attraction of the pole-pieces of the armature and field-magnet bobbins

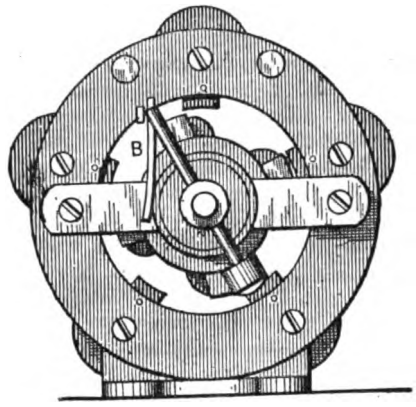

FIG. 4.

as well as that due to the parallelism of the windings of the bobbins as they approach each other during the rotation of the armature, thus obtaining an increased effect from those magnetic lines of force which are ordinarily radiated to create reverse inductive effects detrimental to the efficiency of the machine.

The arrangement is also claimed to avoid the evil effects due to self-induction, for the reason that only a minimum amount of effective wire is in circuit at any time, and that

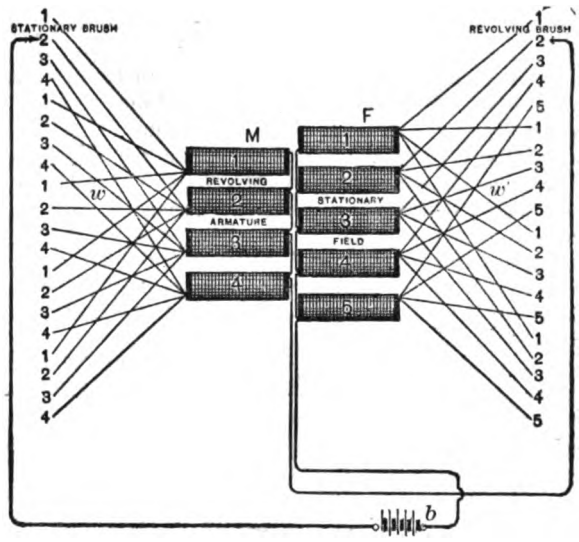

FIG. 5.

only at the time when it is needed to give the best effects. By creating the effective field and armature circuits at stated intervals and only when needed, and permitting all of the field or armature bobbins to rest or be magnetically or electrically discharged at different portions of the armature rotation, heating and waste of energy is said to be prevented. The Foucault currents are also reduced to a minimum by reducing the effective field and armature circuits with their magnetic cores to a minimum while obtaining their maximum effect. The sparking at the brushes is likewise avoided by reason of the fact that there is no magnetic lead in the field or armature, inasmuch as the field travels around just in advance of the armature as each bobbin is cut in

Digitized by Google

Among other novelties which the machine is claimed to possess by the inventor is, that both field and armature circuit are conjointly cut out at different points in the rotation of the armature, thereby utilising only that portion of the combined circuit which is needed to propel the motor or create a current in the machine when used as a dynamo.

The efficiency of this motor is said to be very high, and the machine very light and simple in construction.—*Electrical World.*

THE ADELPHI INSTALLATION.

Among the first to show their belief in the electric light and to act upon that belief were the Messrs. Gatti, who have now one of the largest private installations in the kingdom. It will be remembered by many *habitués* of London that the restaurant almost opposite Charing Cross was one of the first places wherein electricity superseded gas, and so successful has the lighting been considered by the proprietors that they have introduced the system into the Adelphi Theatre, in which, as soon as the installation is complete, gas will become an illuminant of the past. At the invitation of Mr. Blackburn, M.I.C.E., resident engineer to the Edison and Swan Company, by which company the installation has been carried out under Mr. Blackburn's superintendence, we witnessed the lighting, on the reopening of the theatre on the 19th inst., where not only was the new light first introduced, but it was the first night of a new play, "The Union Jack." Under such conditions the responsibility upon the shoulders of the electric light contractors was exceedingly onerous. Not the slightest hitch or difficulty of any kind occurred, and this again in spite of the unfinished state of the installation, many of the details and connections being of a temporary character, as it was not expected that the light would be required at so early a date.

The generating plant, sufficient for 4,000 incandescent lamps, has been supplied by the Edison and Swan Company, and is placed in a building below the street level at Bull Inn-court, adjacent to the theatre. The Adelaide Gallery, the Strand Restaurant, and other buildings are also to be supplied from the same source.

The plant comprises three 150 h.p. Babcock and Wilcox safety-tube boilers, working at a pressure of 140lb. The engines are four of Messrs. Willans and Robinson's double centre valve compound high-speed engines, two of 75 i.h.p., and two of 130 i.h.p. We should like to interpolate a suggestion here in regard to information relating to these engines. In March, this year, Mr. Willans' read a paper before the Institution of Civil Engineers, which was discussed at great length. The paper, and the discussion thereon, contains some of the most valuable information that has ever been contributed on this subject, and as Willans' engines are being so largely used for electric light purposes, we should strongly advise all who can obtain a copy to read the proceedings of the Institution containing the paper referred to. The engines are coupled direct to four Edison-Hopkinson dynamos, two for an output of 105 volts 800 amperes at 425 revolutions, and two for an out-put of 105 volts 475 amperes at about 475 revolutions. The armatures are of the bar type, and the magnets are exceedingly massive, those of the larger machine weighing nearly six tons.

The four sets stand on one solid mass of concrete 6ft. thick, and there is a very marked absence of noise and vibration.

It is anticipated that a very economical result will be obtained, and already at a preliminary trial at Messrs. Willans and Robinson's works, an electrical h.p. (746 watts) in external circuit was obtained from 30lb. of steam per hour, and a return of 82 per cent. of the i.h.p. These results were obtained with comparatively wet steam, and as great precautions have been taken to supply dry steam, still better results should be obtained in practice.

The external circuits will be 12 in number, and two large distributing boards of slate 6ft. 6in. by 4ft. 6in. have been provided. The connections take the form of large brass bars, which can be coupled by means of plugs, so as to make any number of combinations between the dynamos and circuits. In effecting changes sparking is avoided by shunting the plugs through a quick break-switch. The dynamos all work on independent circuits, and one dynamo is always held in reserve, and whenever it has to relieve another already at work any dip in the lights is avoided by first of all bringing it up to full load on a resistance, and then exchanging loads between the two dynamos by the reversal of a commutating-switch.

It is Messrs. Gatti's intention in the course of a few weeks to entirely dispense with the gas service throughout the theatre so far as lighting is concerned. About 1,500 lights are required to light the bars, passages, refreshment-rooms, auditorium, and stage. The auditorium is lighted from the dome by means of eight 200 c.p. Edison-Swan lamps. Ornamental 3-light brackets are suspended round the tiers, and single lights are provided for the occupants of the pit, gallery, and boxes. Duplicate circuits have been provided throughout, and great precautions have been taken with a view to secure absolute safety from fire or possible extinction of the light. The lamps for the floats (footlights) and battens are provided with collars of a special form, each carrying its own cut-out, and having extended terminals making contact directly with the main wires, which are completely enclosed in a slate casing, and on which also the lamp sockets are mounted, proximity of any combustible insulating material to parts developing heat is thereby entirely avoided. All the other conductors about the stage are enclosed in wood casing. They are strongly insulated with indiarubber, and further protected by a sheathing of asbestos tube, and in all places where there is any liability to injury by violence, or by nails being driven through the casing, a lining of sheet-iron is provided.

Lamps of high candle power have been introduced in the construction of the variable resistances required for scenic effects; and it is also arranged to display colour lights when required. As we say, the installation was hardly in its normal state, and when the finishing touches have been given we intend to illustrate the dynamo-room, showing the arrangement of boilers, engines, dynamos, and switch-boards. It hardly comes within the province of an electrical engineer to criticise a theatrical performance, but as all the scribes whose work is of this special description spoke highly of the play, we may add our testimony in the same direction, saying play and performance were good, with this addition, that one of the principal actors is stated to have said that the electric light is far better than gas in every respect, and having once got it they intend to keep it. Too great praise cannot be given to the Edison-Swan Company and to Mr. Blackburn for the admirable manner in which this work has been carried out.

THE INFLUENCE OF THE CONDENSER ON DISRUPTIVE DISCHARGES.

BY E. G. ACHESON.

While investigating some troubles in an arc-light circuit recently, I was led into a series of experiments on the subject forming the title of this communication; and, while the method of experimentation was rather crude, the results obtained are, I think, of a value sufficient to warrant my presenting them to the public.

For the experiments a direct current of an E.M.F. suitable for the work was not at hand, so an alternating one was used, connections being made to the street mains of an electric light plant, the E.M.F. on the circuit being 1,000 volts.

A special transformer was used, having five terminals, the primary forming a portion of the secondary circuit. One of the terminals was connected direct to one side of the experimental working circuit, while by means of a switch, either one of the other four could, at will, be connected to the other side of the circuit. By this arrangement four E.M.F.'s could be had as desired, and, for convenience of expression, I will term these different connection circuits, and number them 1, 2, 3, 4, in the order of their E.M.F.'s.

In order to determine the E.M.F.'s of these circuits, I made a series of 50 measurements of each, using Law's

Digitized by Google

method for direct currents. The condenser was made of a plate of glass with tin-foil on each side, and was found to have a capacity of ·00282 microfarad, and answered admirably for the work.

The condenser being placed in the circuit, would, upon opening the circuit by mean of a key, hold a charge of a value dependent upon the potential of the terminals of the transformer at the moment of opening, and by suitable connections this charge could be discharged through a galvanometer and its exact value determined.

This operation of charging from the transformer, and discharging through a 10,000 ohm mirror galvanometer, was repeated fifty times for each of the four circuits. Of the fifty determinations of the E.M.F. of each circuit, the highest value obtained was assumed to be the true one for its circuit.

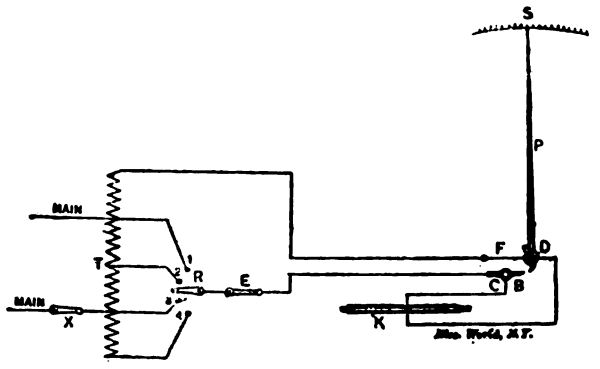

FIG. 1.

By this method I found the four circuits to have the following E.M.F.'s:

Circuit No. 1	.....	580 volts.
,, No. 2	.....	1,110 ,,
,, No. 3	.....	1,690 ,,
,, No. 4	.....	2,114 ,,

The transformer was built for 2,000 volts, with 1,000 volts in the primary circuit. My results showed a little over that amount.

Having now the data necessary for plotting the E.M.F.'s of the circuit, work was directed to the measuring of the spark lengths and the investigation of the influence of the E.M.F. and condenser on them.

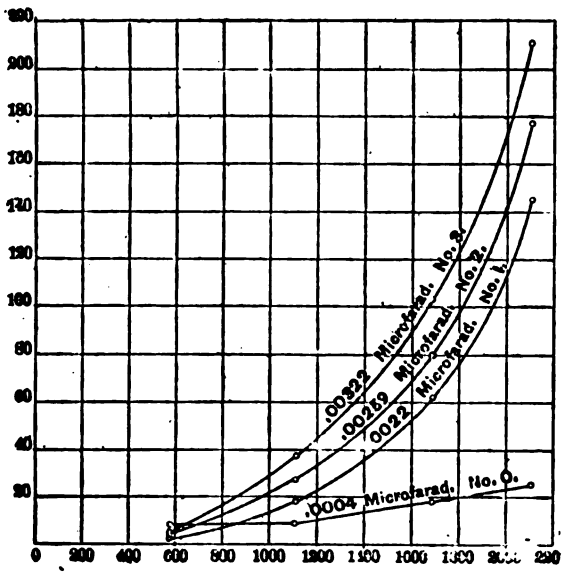

FIG. 2.

Three condensers were made as before described, and carefully measured. The capacities were:

Condenser No. 1	.....	·0018 microfarad.
,, 2	.....	·00219 ,,
,, 3	.....	·00282 ,,

The working circuits without a condenser were found to have a capacity of ·0004 microfarad, and when working up the measurements this capacity was always added to that of the condenser used.

To measure the spark lengths an arrangement of apparatus was used (as shown in Fig. 1), in which A and B are two points, mounted in the posts C and D, the latter being made so as to turn upon its centre. P is a pointer attached to D, S is a scale, T is the transformer, R is a switch for connecting up either one of the four circuits, E is a switch used for opening and closing the experimental circuit; F is a fusible wire connection to protect the transformer, K is a condenser, and X a switch for opening the main line.

The relative distances from D to S and A were as 15 to 1, and the scale was graduated so that a movement of the

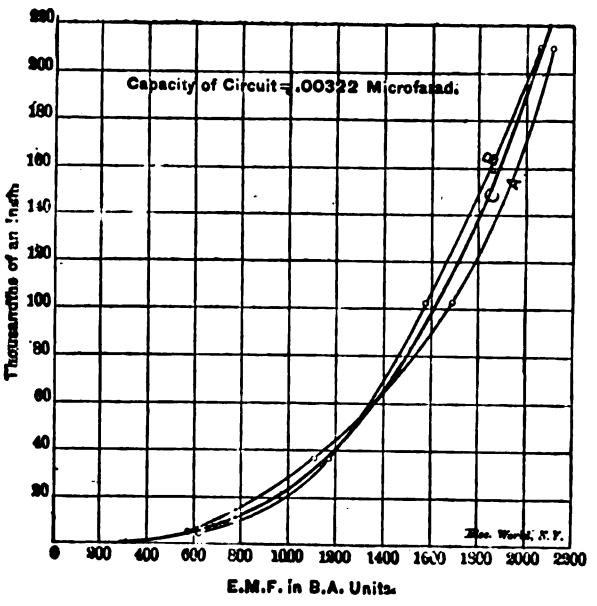

FIG. 3.

pointer over one division moved the point A one one-hundredth of an inch; but owing to the size of the graduation a movement of one one-thousandth of an inch could readily be detected.

The mode of operation was to first set the points so as to just touch each other, and note the reading of the scale; after which the post D was swung upon its centre sufficient to draw A from B such a distance as to prevent a discharge

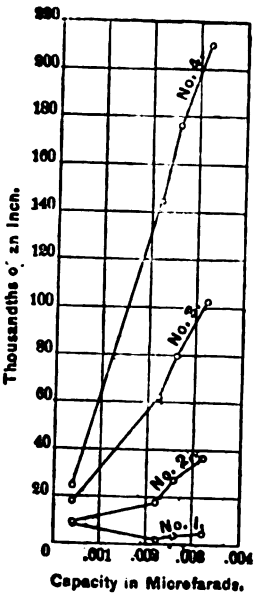

FIG. 4.

occurring across the intervening space upon opening and closing the switch E fifty times. A was then caused to approach B by steps of one one-thousandth of an inch, fifty ruptures of the circuit being made after each advance. When a discharge occurred, note was made of the scale reading, and the difference between it and the first reading was used as a measure of the spark length. The true distance between the points would, of course, be the chord of the arc described by the point A; but the distances were

Digitized by Google

so small that this error was neglected, and the distance measured on the arc. When a condenser was used, it was connected up between the posts C and D, as shown in the figure.

Measurements were made with this apparatus of the spark length produced for each circuit, first without a condenser, and then with each of the three condensers, successively connected to C and D. The results obtained for the various conditions were :

Circuit.	Spark lengths in inches. 1.	2.	3.	4.
Condenser No. 0	·008	·0085	·018	·025
Condenser No. 1	·002	·018	·062	·145
Condenser No. 2	·004	·027	·080	·177
Condenser No. 3	·005	037	·103	·211

Fig. 2 shows the results obtained, plotted as curves, each curve being numbered the same as the condenser used to produce it, No. 0 being the curve determined without a condenser.

In Fig. 3 I have plotted the curves by laying off the capacity of the circuit horizontally, and, as before, representing the length of the spark by the ordinates. The four curves represent the four circuits, and are numbered accordingly.

To determine whether the E.M.F.'s were influenced by a discharge from the magnetic field of the transformer they were remeasured with a condenser having a capacity of ·00077 microfarad. If a discharge occurred, the increase of the E.M.F. above the true value would be proportional to the discharge, and the latter would be subject to the amount of current on the circuit. Hence by decreasing the capacity of the condenser, a lower E.M.F. would result.

The E.M.F.'s as measured were :

Circuit No.	1	625 volts.
,,	2	1,176 ,,
,,	3	1,580 ,,
,,	4	2,058 ,,

The E.M.F.'s of the first and second circuits are higher, and those of the third and fourth are lower, than those obtained with the larger condenser ; but the differences are not greater than would be expected under the circumstances, and, as will be seen from the curves produced, their relations are such as to leave no ground for assuming a discharge from the field.

I would mention that while the first set of E.M.F.'s was determined when the machinery in the laboratory and surrounding neighbourhood was in motion, the second set of E.M.F.'s was measured under the most favourable conditions, the machinery being motionless. In Fig. 4 I have plotted two curves, A and B, in each of which the ordinates represent the length of the spark, and the abscissæ, the E.M.F. in B.A. units.

The experimentally-determined spark lengths for each of the four circuits are the same in both curves, and are marked with circles.

Curve A was plotted from the E.M.F.'s as found with condenser No. 3 ; and curve B, from the results obtained from the small condenser having a capacity of ·00077 microfarad.

The curve C, in Fig. 4, is very nearly the mean of curves A and B, and was calculated by the following formula:

$$\frac{(\text{E.M.F.})^2 \times \textit{charge in coulombs}}{a} = d;$$

where a is a constant for the dielectric, and d the spark length.

The charge being equal to the E.M.F. multiplied by the capacity, the formula may be written—

$$\frac{(\text{E.M.F.})^3 \times \textit{capacity}}{a} = d.$$

In calculating curve C, 135 was taken as the value of a, and d was in inches, the formula then being :

$$\frac{(\text{E.M.F.})^3 \times \text{capacity}}{135} = \text{inches} = \text{length of spark in air.}$$

I am now engaged in determining the value of a for a number of dielectrics, especially those used for insulating conductors in cables, and at the same time experimental work is being done on the determination of the part the phenomenon plays in the operating of underground cables. *Electrical World.*

THE ELECTRICAL DISTRIBUTION OF TIME.*

BY ALLEN D. BROWN, COMMANDER U.S. NAVY.

The subject upon which I have the honour to address you this evening is the Electrical Distribution of Time. Leaving out of consideration the question as to what time is, what its measure and how obtained—questions the answers to which would of themselves serve as a subject for an evening's lecture—I will pass at once to a definition of the title which has been chosen for this address. By this title is understood the causing of the instant shown by a timepiece at a central station to be marked by some apparatus prepared to receive the necessary signal at another station in electrical connection with such central station.

If the apparatus at the receiving station is in the nature of a timekeeper, its operation must be automatic ; and to secure the highest possible accuracy the action of the central timepiece must likewise be automatic. In its best form, then, our title may be said to mean the automatic electrical synchronisation of one or more clocks by a clock at the central station. With this synchronisation may also be associated the registering of the signal upon a chronograph, the ticking of a telegraphic instrument, the firing of a gun, the ringing of a bell, the discharge of a flashing signal, or the dropping of a time ball. In a complete system any or all of these means will be used according to the circumstances of the case under consideration. It is essential, to insure the highest order of accuracy, that the central station shall always be at an astronomical observatory, and preferably at one which is able to devote the services of one or more persons to this special duty. Such work is known briefly as a time service, and its signals as time signals. A brief historical review of the evolution of the time service of to-day will not, it is hoped, prove uninteresting.

As early as 1816, one Ronalds, an Englishman, invented a telegraph which was so dependent upon timepieces for its working, that it may be said to have been a device for the temporal distribution of electricity. He connected two clocks with some 500ft. of insulated copper wire ; upon the seconds arbor of each clock was placed a circular plate of brass, the circumference of which was divided into twenty equal parts, the chief letters of the alphabet and a double series of numbers up to ten being placed in these divisions. In front of this was a second plate in which was an opening through which one letter and figure were visible ; in front of this latter plate was suspended a pith-ball electrometer connected with the wire between the two clocks and also with a frictional electric machine ; this apparatus was in duplicate, one for each end of the line. An electrical pistol was also in circuit when the apparatus was not in use, so that by its discharge the attention of the attendant would be attracted when desired, The manner of using this telegraph was as follows : The clocks were first supposed be accurately synchronised, so that the same letter would appear at the same instant in both plates ; the machine was turned, and by the electricity thus generated, the pistol at the other end of the line was discharged ; the attendant in reply made a signal previously agreed upon, by waiting until this prearranged letter was in sight, and then turning his machine, when the charge would cause the pith-balls of the electrometer to diverge at both stations ; the first operator would cause the discharge of the machine by a touch, the pith-balls would fall together ; the message would then be sent in like manner, as each letter came in sight through the hole in the upper plate, the receiver noting each letter as the balls fell. There were two difficulties in the way of the use of this plan : (1) that of obtaining a current at all times ; (2) the fact that it would be impossible to keep the two clocks always exactly together. This, however, could easily have been gotten over, as the sender could signal when a certain letter was visible, and the receiver noting the one he saw could then tell how much his clock was out of the way. In effect this was the first attempt at telegraphic time signals, and for this reason only is it here referred to.

In 1833 the German mathematician, Gauss, associated with Weber, erected a line of telegraph some five miles in

* *Proceedings*, Franklin Institute.

Digitized by Google

length, connecting the astronomical and magnetic observatories in Gottingen with various other stations. He obtained his current from a crude form of magneto-electric or dynamo machine, and the whole apparatus was of a very unwieldy character; a flattened coil containing some 30,000 feet of iron wire had suspended within its centre a magnetised bar weighing some 30 pounds; upon the suspending wire was arranged a mirror in which was reflected a scale, the latter being viewed through a magnifying-glass.

The dynamo had a pole changer, so that the current could be sent in either a positive or a negative direction, and thus the bar be deflected either to the right or the left, at the will of the operator; by a combination of these deflections a message could be spelled out. By this apparatus, as I have gathered, comparisons of clocks were actually made, and to these gentlemen is therefore due the honour of sending the first telegraphic time signals. Although no particulars of the way in which this time service was operated are on record, it may easily be surmised that the method was somewhat as follows: Probably the hour selected for the signal was noon; two or three minutes before that hour, by the standard clock, a signal would be sent over the line; as the hands of the clock marked the exact hour, one distinct deflection of the bar would be made, at which instant the receiver would note the time shown by his clock; subsequently ascertaining the error of the standard, that of the other would readily be deduced.

In 1840, Mr. Charles Wheatstone announced the invention of an apparatus "enabling a single clock to indicate the same time in as many different places, distant from each other, as might be required." He proposed to accomplish this object by connecting electrically a standard clock with his *electro-magnetic clock*, which latter consisted "simply of a face with its second, minute and hour hands, and of a train of wheels which communicated motive-power from the arbor of the second hand to that of the hour hand in the same manner as in an ordinary clock train"; a small electro-magnet was caused to act upon a peculiarly-constructed wheel placed on the seconds arbor, in such manner that whenever the temporary magnetism was either produced or destroyed, the wheel (and, consequently' the second hand) advanced the sixtieth part of its revolution. On the axis of the scape-wheel of the primary clock was placed a small disc of brass, which was first divided into sixty equal parts; each alternate division was then cut out and filled with wood, so that the circumference consisted of thirty alternations of wood and metal. A very light brass spring was secured to an insulator attached to the clock frame, its free end pressing upon the circumference of the disc; connection having been made between the insulated end of the spring and one end of the wire with which the electro-magnet was wound, the circuit was completed by the other end of the wire being connected to the clock frame through a battery; the primary clock being running, it followed that the circuit was made and broken each alternate second, while the distant dial recorded the advance of its wheel in unison with that of the parent clock. This is practically the same thing as the so-called electric time system of the present day, and it was the first attempt at the distribution of time by electricity. It had the defect common to all such systems, of being applicable to only a limited space, and, in addition, it was subject to the same trouble that besets everyone who proposes to rely upon electricity derived from a battery as a motive-power for any sort of machinery; accidents *will* occur, and a system of time distribution on this plan an accident is fatal to precision.

The completion of the Morse telegraph between Washington and Baltimore, in May, 1844, afforded the means for the next step in the evolution of our subject, and for this we are indebted to a naval officer, Commander Wilkes (afterwards Rear-Admiral), who, associated with Lieut. Eld, transmitted time signals between the two cities. So keen was Wilkes in this matter, and so alive to its importance, that although the telegraph was not completed until the 27th of May, yet on the 9th of June Wilkes was exchanging his first signals, completing his work on the 12th. He used two chronometers, each rated to local time, and thus ascertained the difference of time between the two cities, and hence the difference in their longitude; his determination of this difference was only 3-100 second from that subsequently determined by the Coast Survey when more accurate methods had been devised.

Two years later, in October, 1846, time signals were exchanged between the Naval Observatory, in Washington, and the observatory of the Central High School, in Philadelphia, this being the first use of what has since come to be known as the American telegraphic method of determining differences of longitude. This work was planned under the Coast Survey by Mr. Sears C. Walker, an assistant in that office. The observations were made by Prof. Kendall, in Philadelphia, and Lieutenant Almy, in Washington.

In July and August, 1848, signals were exchanged between the observatory of Harvard College and a private observatory in New York. During this work, Prof. Bond, of Harvard, conceived the idea of an automatic circuit interrupter to be worked by the clock used in the observation. He communicated his ideas to the superintendent of the Coast Survey, and by him was authorised to construct a clock after his plans. This work was not finished until some time in 1850.

In the meantime Mr. Walker, in conversation with Prof. O. M. Mitchell and Dr. John Locke, of Cincinnati, had told them what the Survey desired in the way of an automatic registration apparatus. Both these gentlemen set at work, and Mitchell devised an apparatus which was finally completed in February, 1849. Locke busied himself in the same direction, and twelve days after his talk with Walker he had perfected his apparatus. In this, each of the 60 teeth of a wheel on the seconds arbor of a clock struck the arm of a tilt hammer. When the tooth was in a horizontal position, the other arm of the hammer fell upon a bed of platinum, which was in connection with one pole of a battery, while the fulcrum on which it moved was in connection with the other pole. The circuit was then broken and made at each rising and falling of the hammer. The next step was to connect the clock with some form of registering apparatus, and for this purpose the ordinary Morse register, with its continuous fillet of paper, was used. On the 17th of November, a little more than three weeks after the idea was first suggested to him, Locke had in operation his clock registering its beats over the entire line between Cincinnati and Pittsburgh, a distance of more than 400 miles.

This was the first instance in which time signals were delivered *automatically* by telegraph. As the fillet of paper passed through the register, a continuous record of the seconds was made, with nothing, however, to indicate the beginning of the several minutes; this indication was accomplished by the use of a break circuit key which the observer held in his hand, and pressing at the sixtieth second of each minute, caused the registration to cease for three or five seconds, as might be desired, thus marking the beginning of the minutes. Presumably, Locke was engaged during the following six weeks in perfecting his invention, for it was not until December 30th that he announced to Lieut. Maury, the superintendent of the Naval Observatory, what he had accomplished, and offering it, not only for the telegraphic determination of longitudes, but also "as useful in a local observatory as a faithful and convenient register of observations." On the 5th January, 1849, Maury replied in substance as follows: "I regard it as one of the most important inventions of the age. Feelings of professional pride gave additional zest and warmth to these congratulations. For ages the problem of longitude has occupied the mind of wise men, and commanded the attention of governments. This discovery of yours is the crowning work in the great problem. Permit me to claim this high honour first for my country, and next for the Navy. An American naval officer, Captain Wilkes, was the first to apply the magnetic telegraph to the practical determination of longitude. It greatly lessened labour and refined results. The next and last step has been made by yourself, who also are an ex-officer of the Navy. You have, by your invention, eliminated from the problem the errors arising from comparing the face of one clock with that of another, and made it as easy and practicable to divide seconds into hundredths, as before it was to divide minutes into seconds.

Digitized by Google

By your invention you enable the astronomer to make the ticks of his clock here in Washington to be heard wherever the telegraph leads, and you make the clock to divide those seconds into hundredths."

On the same day he addressed a letter to the secretary of the Navy, informing him of Locke's invention, and recommending it in the highest terms. This letter was made public, and after some further correspondence it was followed by an invitation from the secretary to Locke to come to Washington. The subject of an appropriation was discussed, and after much push on Maury's part, the sum of 10,000dols. was put in the Naval Bill by the House for the purchase of a clock on Locke's plan. This came very near being lost in the Senate, but it was saved by the exertions of the friends of the measure, and became a law on the 3rd of March. By the provisions of the Act the clock was to be erected at the Naval Observatory. This was done, and on the 7th of December, 1849, the clock, with the chronograph attachment, was used for the first time, and proved to be a great advance over the old method, although there was still some difficulty in the matter of accurate registration.

As before stated, in 1850, Prof. Bond, of Harvard Observatory, completed his clock for the Coast Survey, and, in addition, invented an improved chronograph in which the paper was placed upon a revolving cylinder, the driving power of which was so adjusted as to cause one revolution per minute to be made, the record being made by a pen in a continuous spiral line; but, as in Locke's plan of the Morse fillet, there was no means of noting the beginning of each minute automatically. About the same time the cylindrical form was under consideration at Washington, but there were some difficulties which it does not appear were surmounted at this date.

In 1851, the Bond chronograph, with its ingenious driving machinery, known as the spring governor, was taken to England, and there exhibited, eliciting much commendation, and receiving a gold medal at the Great Exhibition of that year. The Astronomer Royal, of the Greenwich observatory, in his report for June, 1851, states that he has adopted the plan of "making a galvanic register of transits in the American manner," but the cylindrical chronograph was not adopted until some three years later—a suggestion by Maury during a visit to Greenwich having enabled Sir George Airy to overcome the practical difficulties which were encountered.

During this same year the observatory at Harvard was connected with the various telegraph lines from Boston, as many longitude operations were being carried on for the Coast Survey. In this manner the attention of such portion of the public as were interested in such matters was drawn to the practicability of obtaining accurate time from the observatory, and in many cases regular arrangements were made for the transmission of the signals throughout Massachusetts and some of the other New England States. Indeed, at present the time service of Cambridge furnishes the chief source of comparison in that section of the country; the observatory at Yale College also possesses such a service, which supplies Connecticut in like manner. The observatory of the Washington University at St. Louis, and that at Alleghany, Pa., also have extensive time service, and there are others covering less ground.

At Washington the Naval Observatory has dropped a time ball since the first occupation of the completed buildings in 1844, following the example set at Greenwich eleven years earlier. At first the dropping was done by hand, upon signal received from the chronometer room; later this signal was sent electrically, and the dropping of the ball was performed automatically by the same signal. This ball served to give the moment of noon not only to the cities of Washington and Georgetown, but also to the Navy Yard and to such vessels as happened to be lying there. No telegraphic signals were transmitted, however, for several years, the Royal Observatory at Greenwich far outstripping us in that respect, as a system of time signals to the important cities and towns of England was in operation as early as 1852. This, of course, was readily accomplished in a country of such small extent, where the difference of any given local time from that of Greenwich is not great; but in our own case, the great extent of longitude and the different local times through what was supposed to be the necessity of the case, conspired to prevent the extension of any such system. Local jealousies had also a part to play, as the railroads running out of Boston would not keep New York time, and *vice versâ*.

With this brief retrospect of the course of events which has made the electrical distribution of time possible, let us return to the subject proper of this essay; and in so doing I beg leave to repeat a portion of the definition with which it began—viz., "By the electrical distribution of time is understood the causing of the instant shown by a timepiece at a central station to be marked by some apparatus prepared to receive the necessary signal at another station in electrical connection with such central station. It is essential, to secure the highest order of accuracy, that the central station shall always be at an astronomical observatory, and preferably one which is able to devote the services of one or more persons to this special duty." In order to a fuller understanding of the functions of an observatory, it will be necessary to call your attention to some of your early instructions in astronomy. The interval between two successive transits, or meridian passages, of the sun, is an apparent solar day; owing to the unequal motion of the earth in its orbit (or to put the statement in another form, to the apparent unequal motion of the sun in the ecliptic) two successive apparent days are not of the same length. As a constant standard of time is necessary, it has been found essential to assume an imaginary sun moving in the equinoctial (or the plane of the earth's equator) at a uniform rate, which is the mean rate at which the true sun moves in the ecliptic; the interval between two successive transits of this imaginary mean sun is a mean solar day, and in a clock keeping mean time, the hands would (if the clock were correct) point to 12h. 0m. 0s. at the instant of transit, which is known ordinarily as noon. As a matter of fact, however, the sun is rarely used at observatories for the determination of time, but stars are employed instead; this is done, not only because the tables of the positions of the stars are more accurate, but because several stars can be observed at about the same time, and the results deduced from these observations made to serve as checks upon each other. The interval between two successive transits of the same star is called a sidereal day; this interval is constant, and is (like the mean solar day) divided into twenty-four hours. Each star comes to the meridian at an earlier period than on the day preceding, if the transit be noted by a mean-time clock; the difference between a star and a sidereal day is 3m. 56s.—and hence the sidereal 0h. is constantly getting ahead of the solar 0h., so that it is always necessary to reduce the *sidereal* time found by the star observations to that used in ordinary life, or to *mean* time. The positions of stars are given in the tables by their *declination* (similar to terrestrial latitude) and their *right ascension* (similar to terrestrial longitude); the right ascension of the star being reckoned from the celestial prime meridian, it follows that when any given star crosses the meridian, the sidereal clock should show the time given in the table as the right ascension of such star; the difference between the time actually shown by the clock and this right ascension is the error of the clock; comparing then the time shown by the sidereal clock with that shown by the mean time clock, we find the error of the latter. This is briefly the method followed by all observers, and hence is common to all systems of time signals. We have, then, as essentials of any such systems—(1) an instrument for observing the transits of stars; (2) a sidereal clock; and (3) a mean time clock. This mean time clock (like all timepieces) will not run accurately, its rate varying, being sometimes less and sometimes greater The pendulums of such clocks are generally very well compensated for changes of temperature, but it has been found that the density of the air has a decided influence upon the rate at which the clock runs; when the barometer is high, the clock loses on its rate, gaining when it is low. In order, then, that the time which is sent out over the wires should be correct, it is necessary either to have some arrangement for correcting the standard mean time clock so as to make it correct, or else to have a similar clock which can be likewise corrected; such a clock is known as a transmitter.

Digitized by Google

The system of the Greenwich Observatory being the oldest in point of time merits the first description. The standard sidereal clock is a remarkably fine piece of workmanship, having, in addition to a peculiarly constructed compensated pendulum, an auxiliary apparatus intended to still further aid in the compensation for changes in temperature, which it would be impossible to describe intelligibly without a drawing. There is also an arrangement for counteracting the influence of the variations in the density of the air, which is the invention of Sir George Airy, and is very ingenious; two bar magnets are secured to the bob of the pendulum diametrically opposite each other, one with the north pole down, the other with same pole up; below these at a distance of about four inches is a horseshoe magnet which hangs on one end of a walking-beam, to the other end of which is attached a float resting on the surface of the mercury in the cistern of a specially constructed barometer; with a rise in the barometer the horseshoe magnet rises nearer the bob and thus exerts a stronger influence upon the swinging magnets, causing the pendulum to oscillate more rapidly: the contrary takes place when the mercury falls. Notwithstanding all these refinements the published records of the observatory show that the clock does not run with perfect accuracy, a variation of its daily rate as large as 1·15 seconds being recorded in a year. It does, however, run with but slight variations of rate from day to day; still it shows as great a loss as one minute in six months; it is supposed to be regulated to lose a small amount daily, but the records show that it occasionally gains as much as half a minute in five or six months. I mention this here in order to show you that those people who talk about their clocks or watches running to within a few seconds a year are probably somewhat wide of the truth. This standard sidereal clock registers its beats upon the chronograph used in observing transits, controls the remaining sidereal clocks in different rooms of the building, and finally drives (in unison with itself) a sidereal chronometer. The controlled clocks are upon the Jones' system (as modified by Sir George Airy); in this system the secondary clocks are required to be quite as good time-keepers as the primary one, which makes it too expensive for general use among the public. As used at Greenwich, the standard clock closes a circuit in which the controlled clocks are placed every second; on the pendulum of each of the latter is a magnet, which at the end of its swing enters a coil of insulated wire; as the current passes the effect is to hold the magnet within the coil, and hence to place the pendulum in a definite position, which corresponds in effect to that of the pendulum of the primary clock; this closes the circuit by means of a wheel on the seconds arbor, which presses upon a spring at each forward motion. The sidereal chronometer already spoken of in this connection is constructed practically upon the same principle as those of Wheatstone, referred to in the early part of these remarks.

This sidereal chronometer is in the time service room and is used for the purpose of comparison with a similarly-constructed mean time chronometer, which is driven by the mean time clock now to be described. This is essentially a galvanic clock of peculiar construction, and of which I imagine there are but few existing. As the pendulum swings to the right it closes a circuit through the coils of an electro-magnet which actuates a peculiar mechanism, by which, as the pendulum swings to the left, a weight is caused to impinge upon the pendulum, thus giving it the impulse which in an ordinary going clock it receives from the weight or spring; this impulse is given at each alternate vibration. At each extremity of the swing of the pendulum it closes a circuit which, acting upon the coils of two electro-magnets, alternately attracts and repels the opposite ends of a balanced polarised armature; this rocking motion is readily converted into a rotary one, causing the seconds hand to revolve, and, by the usual device of a train of wheels, the minute and hour hands also; there are several clocks driven by this pendulum, including the mean time chronometer just mentioned as being in the time service room. The apparatus for correcting the error of the standard mean time clock consists of a magnet secured to the pendulum which swings over a hollow coil of insulated wire attached to the clock case; if a current be passed through the coil in one direction the magnet on the pendulum is attracted and the oscillations are more rapid; if a current be sent in the opposite direction, the contrary is the case; a switch in the time service room serves to operate this arrangement when desired, and the battery is so arranged that it will accelerate or retard the pendulum at the rate of one-tenth of a second in a minute. The practical working of the observatory portion of the time service is as follows:—The error of the standard sidereal clock is obtained by means of star observations as before described; at 9 a.m. daily, the mean time and sidereal chronometers in the time service room are compared by what is known as the eye and ear method—that is to say, the observer waits for the coincidence of the beats of the two instruments and notes the time shown by each at this instant; applying the error of the sidereal clock to the time shown by the sidereal chronometer, the correct sidereal time is found; by a comparatively simple operation the corresponding mean time is found, and from this the error of the mean time, chronometer, or what is the same thing, the error of the standard mean time clock. Suppose that this clock is found to be one second slow, the switch to the coil in the clock is turned in the accelerating direction for ten minutes, during which time the pendulum is swinging faster than usual, and at the end of this period the clock has gained the necessary second; and not only the standard, but all the clocks that are driven by it. In this condition the standard is in readiness to be used as a transmitter; it is in circuit which is closed automatically every hour by the operation of wheels within the clock itself. The closing of this circuit operates a relay which transmits a single beat (that of 0 minutes and 0 seconds of the exact hour) to the General Post Office in London and also to the station of the railway leading to Deal. At this latter point a time ball is erected, and is dropped by the hourly signal sent at 1 p.m. The hourly signal is also transmitted over certain private wires belonging to various jewellers for the purpose of comparing their timepieces. In one case at least this signal is also used for the purposes of distribution.

The line to Deal is for a short time virtually under the control of the observatory, so that a return signal is sent which announces the fall of the ball. A very ingenious adaptation of the galvanic clock described as the mean time standard is in use on this circuit. At a certain point where the line to Deal is looped in, this second clock is placed. It is regulated so as to have a gaining rate of several seconds, so that at 1 p.m. it is always too fast. When that hour is shown by the clock, the circuit which operates the electro-magnet and thence the clock train is switched out automatically, and the Deal loop is switched in. The pendulum continues to swing until the passage of the signal from the observatory opens the circuit and the clock then moves on, showing the exact Greenwich time as it starts.

ELECTRIC LIGHT AT BATH.

At a meeting last week of the Council the Electric Light Committee presented a list of tenders received for lighting the following streets of the city:—Old Bridge, Dorchester-street, Southgate-street, Stall-street, Union-street, Burton-street, Old Bond-street, Edgar-buildings, York-buildings, Princes-buildings, Fountain-buildings, Oxford-row, Belmont, Alfred-street, Bennett-street, Saville-row, Circus, Brock-street, Royal-crescent, Gay-street, Queen-square, Charles-street, Seymour-street, Kingsmead-street, James-street, Kingsmead-square, Westgate-street, Sawclose, Upper Borough Walls, Wood-street, Green-street, New Bond-street, Broad-street, Northgate-street, Bridge-street, Argyle-street, Laura-place, Pulteney-street, Sydney-place, Edward-street, Darlington-street, Raby-place, High-street, Cheap-street, Orange-grove, Terrace Walk, North Parade, South Parade, and Manvers-street.

Seven tenders had been received, and Mr. STURGES now moved that that of Mr. H. G. Massingham be accepted. Mr. Massingham, he said, offered the system which had proved most successful—the Thomson-Houston—an illustration of which was given in High-street on the occasion of the Jubilee; his tender was the lowest; and Mr. Massingham was only acting as the mouthpiece of a number of well-known citizens, who might be depended upon to do everything they could to make the light a success. The expense of the light in the district named would be only £203 annually more than the cost of gas—or 20 per

Digitized by Google

cent. more against the 50 per cent. more which was at one time anticipated. He dwelt on the importance of the city being to the fore in all improvements, and said that as the adoption of electric lighting out of doors would certainly lead to its introduction into shops and public buildings the health of the community would be improved and life lengthened. The contract proposed was for seven years, as no company could be found to put in an expensive installation with only a year guaranteed, but the contract would be so prepared that if the light did not prove successful it could be terminated at three or six months. The system of overhead wires was recommended; he knew that would be objected to, but it was the cheapest, and installation would be more perfect. He proposed that Mr. Massingham's tender be accepted.

Alderman MURCH, who seconded, said he had something like a feeling of regret at the prospect of parting with an old friend which had served them so faithfully for a great many years. But he was sure the Council would feel that gratitute for past good need not deter them from a prospect of future enjoyment. He trusted that Bath would continue to progress on the same lines on which she had advanced in late years, and that she would be prominent among the cities of the kingdom for the introduction of the electric light.

Alderman OLIVER said they were asked to make a great change—to do away with a light with which they were well acquainted, and to distribute an agent in lighting of which they knew little. Changes of this kind required great consideration and ample discussion, and this he did not think had been given to the subject. He was not at all interested in gas or electricity, and he did not say that the electric light would not be the light of the future; but he would say that it was now in its infancy. It had not developed as it should have done, and he contended that it would be wrong to saddle the ratepayers with additional expense, and to incur risk and uncertainty. Seven towns were mentioned in a previous report as having adopted the light. Well, in Brighton, the first named, it was not used; in Chesterfield it had been discontinued as too uncertain and expensive, and had been replaced by gas, and the town, as a penance for its electric fever, had turned the engine-shed into a Salvation Army hall, which, he had no doubt, would do more good; at Leamington it was admitted to be a failure, and the cost was double; at Eastbourne the cost of certain lamps was £560 compared with £240 for lighting the same area with gas, and the installation had proved most expensive and unsatisfactory in Greenock.

Dr. TUCKETT: Where did you say?

Alderman OLIVER: Greenock, in Scotland.

Dr. TUCKETT: I was there the other day and didn't see anything of it.

Alderman OLIVER, continuing, stated that the cost of the light in Taunton was said to be double that of gas. The report brought up some time ago was defective and unsatisfactory, and so was that presented now; it did not give the relative cost of gas and electricity, nor show the number of gas lamps which would be displaced. Seventy lamps were estimated to light fifty streets; which on an average was three lights to two streets. Would that be enough? He doubted it. Then there was the danger of overhead wires; and he understood if a man touched the wires during the time the installation was on he would instantly be a subject for a coroner. It was a question whether people living in the parts not to be lighted with electricity would agree to pay for the new light in other districts. The rate had increased greatly of late, and they should not be further burdened without the city receiving any advantage.

Alderman GIBBS also opposed the resolution. He contended that the electric light was as yet in its infancy, and would probably before long be rendered more perfect in these days when science made such rapid strides. Another objection was that the light would not be distributed fairly and equally. For instance, the important ward of Lyncombe and Widcombe would not have an electric lamp in it according to the present proposal. The limited area would not be permitted for long, and if it were extended they must consider the heavy expense that would accrue. Then was Bath a place in which this improved light was wanted? It was a quiet town, and had not the same traffic in the dark which was to be found in places where electricity had not been adopted. Mr. Sturges, when wending his way home to his London lodgings from the Opera House (laughter) would find men turning down the gas lamps, and that was in the city of London, a place where it was essentially necessary to have as much light as possible. There was no immediate need for the electric light, and by adopting it they would increase the present taxation, which in many cases was found exceedingly heavy by the poorer classes, who, for the most part, would be in bed when the electric light was shining out of doors. They must also consider the evil and uncertainty of disarranging the present system.

At 1.30, on the suggestion of the Mayor, the discussion and the other business on the agenda paper were adjourned.

The following communication, which was enclosed with Mr. Massingham's tender, the contents of which we referred to in a note last week, was sent for publication:—

Bath, June 30, 1888.

Dear Sir,—I send the enclosed tender at the request of those citizens of Bath who are desirous of seeing our beautiful city progress with the times. The tender is based upon an estimate to pay only 5 per cent. per annum upon the capital employed, provided everything is conducted upon the most economical scale. I believe it is the lowest tender that has ever been made for public electric lighting, and, if accepted, those citizens who are acting with me will at once form a local company for supplying the light permanently for private as well as public use, so that the bathing establishments and other places can at any time be lighted. I recommend 69 lamps, but if the North and South-parades are included, which are not shown on the official plan, two more lamps will be wanted, making a total of 71. These 71 arc lamps being placed principally at the junction of streets, displace 315 gas lamps, which I have reckoned at £3 8s. each, making £955 10s. They also displace 18 large lamps, 12 of which I have considered as costing £10 3s. 1d. each, and 6 £8 8s. 7d. each, making £171 16s. 6d., a total of £1,127 6s. 6d.

The total cost of the 71 arc lamps, reckoning them at £18 17s. 6d. each, is £1,330 2s. 6d. This is a lower price than I have ever led the Council to expect. The sum I named when first asked being 50 per cent. more than gas, whereas this estimate is only 20 per cent. more, though giving several hundred per cent. more light.

If this tender is accepted I would suggest, instead of terminating the district at the Circus, the Council extend it through Brock-street to the end of the Royal-crescent, and instead of leaving off at the bottom of Pulteney-street, extend it to the end of Sydney-place on each side of that street, returning through Darlington-street, Vane-street, and Edward-street, taking in Raby-place. This would require ten additional arc lamps, costing but a trifle more than the present gas.

H. G. MASSINGHAM,
Originator of the Taunton Installation, and Managing Director of the Taunton and Exeter Electric Lighting Companies.

The Bath Town Council, on Tuesday last, by 22 votes to 12, decided to light 50 principal streets with electric light. Several shareholders of the Gas Company in the Council did not vote. Mr. Massingham's tender was accepted.

LEGAL INTELLIGENCE.

THE SIMPLEX ELECTRIC LIGHT AND PLANT COMPANY, LIMITED, v. COOPER AND CRAIG.

Mr. Bigham, Q.C., and Mr. Hopkinson were counsel for the plaintiff company, and the defendants were represented by Mr. Gully, Q.C., M.P., Mr. Yates, and Mr. Brierley.

Mr. Bigham said the action was brought to recover the price of installing the electric light at the colliery of the defendants, in Staffordshire, and also to recover several items for goods supplied and work done.

The defence, briefly stated, was that the plaintiffs did not do their work to the satisfaction of the defendants. After opening the case, Mr. Bigham suggested that the better course would be to refer the matters in dispute to a practical electrical engineer.

The **Judge** said he did not like to shrink from any duty that was cast upon him; but, in any event, a considerable portion of the case must be referred, because to some extent the case was one of accounts, and under all the circumstances he thought the parties would be more likely to arrive at a satisfactory settlement by referring the disputed points.

After counsel and clients had consulted together—

Mr. Gully announced that it had been decided to refer the case to a gentleman to be agreed upon between the parties. If the parties could not agree upon the referee, application would be made to his Lordship to nominate a gentleman.

COMPANIES' MEETINGS.

INDIARUBBER, GUTTA PERCHA, AND TELEGRAPH WORKS COMPANY.

The half-yearly general meeting of the Indiarubber, Gutta-Percha, and Telegraph Works Company, Limited, was held on the 19th inst. at the City Terminus Hotel.

Mr. S. W. Silver presided, and, in moving the payment of an interim dividend of 5 per cent., observed that the working of the Company so far this year had been of a satisfactory character.

Mr. Neil Bannatyne seconded the motion.

In answer to questions, the **Chairman** stated that the telegraph works were only partially employed. They lost no opportunity of seeking employment for their ships, and one of them had been engaged in the service of the Italian Government. Their books were made up only once a year, but the impression of the Directors was that the dividend now proposed had been earned out of the half-year's profits.

Mr. Gray (the managing director), in further reply to **Mr. Webber**, said he was perfectly certain that their coal was bought well, and in the market where they got them cheapest in price and best in quality.

The resolution was carried.

MAXIM-WESTON ELECTRIC COMPANY.

An extraordinary general meeting of the Maxim-Weston Electric Company, Limited, was held on the 19th inst., at the City Terminus Hotel, having been summoned by a requisition from shareholders to appoint additional Directors. Mr. Hugh Watt, M.P., presided.

Digitized by Google

On the motion of **Mr. Hirsch**, it was resolved to add five Directors to the Board, and, subsequently, after some discussion, it was agreed, on the motion of **Mr. Hildyard**, seconded by **Mr. White**, to appoint the following gentlemen members of the Board:—Messrs. J. M. Klenck, John Marks, G. H. Hildyard, W. D. Harvist, and J. G. Couchman.

The Chairman afterwards made a statement reviewing the history of the Company, expressing his readiness at all times to act with any additional members on the Board, and giving a hopeful view of the Company's prospects.

A vote of thanks having been passed to the committee of investigation, the proceedings became informal, and Mr. Watt having vacated the chair, Mr. Louis Swaby, one of the old directors, was invited to preside.

A long and animated discussion then followed on a suggestion by Mr. John Newton that the committee should receive a certain sum in consideration for their services in investigating the affairs of the Company. Ultimately it was agreed, with a few dissentients, to recommend the Directors to reimburse the committee for their outlay in the interests of the shareholders a sum not exceeding 100 guineas.

Another angry discussion ensued on a suggestion as to whether Mr. Watt should be asked to retire from the Board, but no decision on the subject was arrived at, and the meeting ended in disorder.

EASTERN TELEGRAPH COMPANY.

The thirty-second ordinary general meeting of the Eastern Telegraph Company, Limited, was held on the 19th inst. at Winchester House, Old Broad-street, under the presidency of Sir John Pender.

The **Chairman** stated that the revenue for the past half-year to March 31 last had been £359,706, or £27,844 in excess of the revenue for the corresponding period of the previous year. From their investment in the Eastern and South African Company, nearly all the shares in which belonged to the Company, they had received £31,200, or £7,800 more than in the previous year. Their return from the Black Sea Telegraph Company, owing to an interruption in the cable, had been £1,300 less; and on their ordinary shares in the Direct Spanish Telegraph Company, in which they had a controlling influence, they had received £676, against *nil* in the corresponding period of the previous year. The Company had now "turned the corner." The total working expenses of the Company in the past half-year had been £87,134, or £4,099 more; and the expenses attending the repairs and renewals of cables had amounted to £38,412, or £5,491 less, although they had charged under that head the whole cost of duplicating the Zantre-Patras section of about 60 miles. After charging all expenses, including income-tax, interest on debentures, debenture stock, and preference shares, they were able to pay a dividend of 5 per cent. and a bonus of 1 per cent. for the past year, and to transfer to the general reserve fund £75,000, leaving £884 to carry forward. They had charged the whole cost of triplicating the Porthcurnow-Malta cable and the extension to Zante to the reserve fund, which was thus left at £342,338. With the special reserves stated in the balance-sheet, their total reserves amounted to £362,606. They had also charged the amount expended on the new screw steamer, "Amber," to the maintenance ships' fund. The issue of the four per cent. mortgage debenture stock, to pay off the Five per Cent. debentures, was now complete, and the premium of £2,366 on its issue had been credited to the reserve fund. The total capital amounted to £5,900,000, and the expenditure to £5,965,000. They proposed to make arrangements to dispose of the £62,000 of six per cent. debentures of the Direct Spanish Company, and when that was complete the capital and the capital expenditure would practically balance. They would then be able to increase the investments on account of their reserve funds. They had recouped the loss incurred through the reduction of rates forced on them at the Berlin Telegraph Conference. He concluded by moving the adoption of the report and the payment of the dividends and bonus recommended.

The **Marquis of Tweeddale** seconded the motion.

In reply to **Capt. Goodsall**—

The **Chairman** stated that the length of cable between Porthcurnow and Zante was 2,728 miles. The cost of the "Amber" was £29,000 odd.

The motion was carried unanimously.

DIRECT UNITED STATES CABLE COMPANY.

The twenty-second ordinary general meeting of the Direct United States Cable Company, Limited, was held at Winchester House, Old Broad-street, on Friday last.

Sir John Pender, who presided, stated that the revenue for the half-year, after deducting out payments, and including income-tax refunded, had been £17,508, and the working and other expenses, including income-tax, but exclusive of the cost of repairs, had been £15,277, leaving a balance of £2,231 as the net profit of the half-year, making, with £9,911 (composed of £6,899 interest and profit and £3,012 of principal) transferred from the reserve fund account, a total of £12,142, with which two interim dividends of 2s. each had been paid. A final payment of 2s. a share for the quarter ended the 30th ult. was now proposed, making, with the three interim dividends already paid, a total of 2 per cent. for the financial year. The revenue, owing to the low rates current, showed a reduction of £6,064 as compared with that of the corresponding period of last year; and the expenses and other payments exhibited a reduction of £628. The cost of the current repairs amounted to £25,222 to the 30th ult. That sum was at present standing in the balance-sheet, but it would be dealt with later on, together with the cost of completing the repairs. The investments continued worth much more than they had cost the Company. When he last addressed them he went fully into the details of the negotiations then going on in regard to raising the rate. The 6d. tariff had been given a thoroughly fair trial in the last two years, and he had never believed it would give them a fair dividend. The negotiations had been going on more or less ever since the last meeting, and they had culminated now in the Anglo-American, the Western Union, the Commercial, and the Direct Companies seeing the folly of continuing the tariff of 6d. a word any longer. Representatives of the French Company would be seen by them on Monday, and he saw no reason for supposing they would not agree with the other companies interested. He thought they might assume that they would agree, and in that case the rate would be raised to 1s. a word on the 15th prox. If they obtained at the 1s. rate all the traffic they now had at 6d. a word, they would be very much in the position they were in when the tariff was 2s. a word, and when they were enabled to pay a respectable dividend. The 1s. tariff would be given a year's trial, and if the public did not support them at that rate to the extent they now did, it would be for their consideration a year hence whether any further change should be made in the tariff. It would be distinctly understood that there were to be no rebates. He had hoped to be able to inform them that their cable was in thorough working order again; but they had lifted the cable from 2,200 fathoms of water and taken out one important fault. He concluded by moving the adoption of the report, and a final dividend of 2s. a share.

Mr. William Ford seconded the motion.

In reply to questions, the **Chairman** stated that the old pool would continue. The Commercial Company had simply agreed with them as to raising the rate, in connection with which the pooling arrangement was not involved. The cost of the repairs to the cable would be charged to the reserve fund. When they could better afford it, he would be very glad to agree to the appointment of a managing director. Meantime they were effecting a considerable saving, and their interests were completely safeguarded. He had himself been acting practically as the manager of the Company. It was unfair and altogether wrong to treat the dividend now paid as if it were the regular distribution. The cable was last year removed to a position of far greater safety at Halifax.—The motion was then adopted.

A discussion followed on the question of the re-election of the retiring Directors, it being argued by some speakers that five Directors were sufficient, and that the fees of the Board ought to be less.

The **Chairman** stated that before the present Board took office and rescued the Company from ruin the shareholders had never received a dividend, while for some years the Directors had paid them a dividend of 5 per cent., and had also formed a large reserve fund.

Ultimately the retiring Directors were re-elected, as were also the Auditors.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The traffic receipts of the Brazilian Submarine Telegraph Company, Limited, for the week ending July 20 amounted to £4,633.

Western and Brazilian Telegraph Company.— The traffic receipts of the Western and Brazilian Telegraph Company, Limited, for the week ended July 20, after deducting the "fifth" of the gross receipts payable to the London-Platino Brazilian Telegraph Company, Limited, were £3,924.

Submarine Telegraph Company.—The accounts of the Submarine Telegraph Company for the half-year ended June 30, 1888, submitted to the Board, show a balance, subject to audit, which enables the Directors, after adding 15 per cent. of the gross receipts to the reserve fund, to recommend a dividend at the rate of 13½ per cent. per annum.

Cuba Submarine Telegraph Company.—At a meeting of the Directors of the Cuba Submarine Telegraph Company, Limited, held on Wednesday last, the audited accounts for the half year to the 30th June were submitted, and it was resolved, after providing for the dividend on the preference shares, and placing £6,000 to the reserve fund, to recommend the payment of a dividend on the ordinary shares at the rate of 9 per cent. per annum, tax free, leaving £1,195 to be carried forward to the current half-year's account.

Globe Telegraph and Trust Company.—The report of the Directors of the Globe Telegraph and Trust Company, Limited, for the year ending 18th of July, 1888, shows that the net revenue of the Company, after deduction of expenses, amounted to £168,053, which, with the balance of £1,442 brought forward, makes a total of £169,496. From this amount there has been distributed the sum of £114,023 in interim dividends, leaving an available balance of £55,472. The Directors recommend the payment of a final dividend for the year of 3s. per share on the preference shares and 3s. per share on the ordinary shares, making, with the former distributions, a total dividend for the year of 6 per cent., less income-tax, upon the preference and 3½ per cent. net upon the ordinary shares (against 2⅞ per cent. for the preceding year), and carrying forward a balance of £2,107.

NEW COMPANIES REGISTERED.

City of Westminster Electrical Syndicate, Limited.—This Company intends to erect a central or other station, &c., for the creating, producing, generating, accumulating, distributing, storing, and supplying electricity, electrical motive force, or any similar agency for lighting, heating, motive signalling, telegraphic, telephone, and other purposes, in the city and liberty of Westminster and elsewhere, and to lay down, establish, fix, and carry out all necessary wires, lines, communications, accumulators, lamps, and works for such purposes, or any of them. The capital of the Company is £10,000, divided into 10,000 shares of £1 each.

PROVISIONAL PATENTS, 1888.

JULY 13.

10,194. **Improvements in electrical switches.** Arthur Cecil Cockburn, 2, Aubert-park, Highbury, London, N.

10,209. **An improved electric regulator.** Frédéric Victor Maquaire, 53, Chancery-lane, London, W.C.

10,220. **Means or apparatus for automatically establishing electrical contact for motion and light purposes on receipt of a coin in views or other boxes, said coin being freed at a fixed period following the motion.** William Speirs Simpson, 166, Fleet-street, London.

JULY 14.

10,245. **Improvements in and connected with electrical safety cut-outs.** Ernest Perrett, 77, Chancery-lane, London, W.C.

JULY 16.

10,299. **Improvements in electric logs.** Nesbit Willoughby Wallace, 53, Chancery-lane, London, W.C. (Percy Scott, H.M.S. "Edinburgh," Malta.)

JULY 17.

10,363. **Improvements in and relating to multiple telegraphy.** Ernest Jules Pierre Mercadier, 169, Fleet-street, London.

JULY 18.

10,415. **Improvements in the production of hydrated proxide of iron from galvanic dry elements.** C. Gassner, jun., 33, Southampton-buildings, Holborn, London. (Complete specification.)

10,434. **Electric material for medical and curative purposes.** Thomas Field, jun., 11, Queen Victoria-street, London, E.C.

10,437. **Improvements in printing telegraphs.** John Edward Wright and John Moore, 24, Southampton-buildings, London, W.C.

COMPLETE SPECIFICATIONS ACCEPTED.

JULY 19, 1887.

10,116. **Improvements relating to apparatus for the automatic delivery of goods, the display of advertisements, the imparting of electric shocks, and similar purposes.** John Stewart Wallace, 45, Southampton-buildings, London, W.C.

10,131. **Improvements in meters or apparatus for measuring electricity.** George Forbes, 24, Southampton-buildings, London, W.C.

JULY 20, 1887.

10,157. **Improvements in and connected with apparatus for transmitting and receiving electrical signals.** Thomas Alexander Garrett, 80, Abingdon-road, Kensington, London, W.

AUGUST 17, 1887.

11,252. **Improvements in secondary batteries or electrical accumulators.** Henry Mower, 47, Lincoln's-inn-fields, London.

SEPTEMBER 2, 1887.

11,901. **Improvements in lamp-holders or sockets for incandescence electric lamps.** Ronald Augustus Scott, 331, King-street, Hammersmith, Middlesex.

SEPTEMBER 5, 1887.

12,015. **Improvements in incandescent electric lamps.** Wilhelm Lönholdt, 45, Southampton-buildings, London.

SEPTEMBER 19, 1887.

12,683. **Improvements in the manufacture of spongy lead suitable for electrical accumulators.** François Marie Arthur Laurent-Cely, 169, Fleet-street, London.

SEPTEMBER 20, 1887.

12,718. **Improvements in electrical speed indicators.** James Tate, Sunbridge Chambers, Bradford, Yorkshire.

MARCH 13, 1888.

3883. **Improvements in electrical devices for type-writers** Alfred Julius Boult, 323, High Holborn, Middlesex. (James Francis McLaughlin, United States.)

MARCH 19, 1888.

4221. **Improvements in the construction of holders for incandescent electric lamps.** Theophilus Coad, 10, Thorpe-terrace, Thorpe-road, Forest Gate.

MAY 29, 1888.

7852. **Improvements in or relating to central station apparatus for system of electric distribution by alternate currents.** William Phillips Thompson, 6, Lord-street, Liverpool. (George Westinghouse, jun., United States.)

SPECIFICATIONS PUBLISHED.

7185. **Electro-propulsive motors, &c.** W. H. Akester. 8d.

10,177. **Electric batteries.** E. L. Mayer and H. Liepmann. 6d.

11,390. **Secondary batteries.** J. S. Stevenson. 8d.

11,417. **Electrical connection with moving bodies.** T. A. Garrett. 8d.

11,502. **Dynamo-electric and electro-dynamic machines.** E. F. H. H. Lauckert. 6d.

11,816. **Medical magnetic appliances.** R. Lonsdale. 8d.

13,758. **Electrical apparatus for dental operation.** A. J. Boult. (Smith and Kimble.) 8d.

1888.

7536. **Galvanic batteries.** B. Willcox. (Whittier.) 4d.

NOTES.

The Stockport Gas-Engine.—The Stockport gas-engine is coming much into favour.

Extinguished by a Rocket.—Forty arc lights were extinguished at St. Louis on the night of the fourth of July jubilation by a sky-rocket, which broke the wire in its flight upwards.

Motors for Sewing Machines.—A large costume establishment in Buffalo, N.Y., has a 5 h.p. Sprague motor fitted up to drive all the sewing-machines used in the establishment.

Tender Wanted.—The Cowpen District Local Board (Blyth, Northumberland) are inviting tenders for lighting their district by electric light. The Surveyor to the Board will supply particulars.

North Metropolitan Tramway Company.—At the recent meeting it was stated that, by the next half-yearly meeting, it was expected that many of the cars would be run by electricity.

The Richmond Electric Road.—The passenger traffic on the Richmond, Virginia, electric tramway was very successful on the fourth of July holiday. As many as 17,108 passengers were carried.

Telephone in Vienna.—The charge for telephone in Vienna has been reduced to £8 a year. Many new subscribers have joined at this rate. The total is now 1,200, and new telephone wires are being laid underground.

Richmond.—We see from the local papers that Mr. J. N. Shoolbred has written to the Richmond Vestry, to ask them to assure the West Middlesex Electric Lighting Company that they have already power to electric light Richmond themselves.

Tender Required for Exeter.—Under date July 18, the Town Council of Exeter advertise for tenders for lighting with arc light for a period of seven years. A deposit of two guineas, to guarantee a *bonâ fide* tender, is required for copy of conditions, which can be obtained at the town clerk's offices, 15, Bedford-circus, Exeter.

Arc Lights on Excursion Steamers.—The use of electric light on board ship is extending to the excursion steamers in America. The Van Depoele Company of Chicago has recently supplied a plant for this purpose, consisting of 15 arcs and 40 incandescent lamps.

What they found necessary.—The *Electrical World* notices the filing of a paper in the American courts from the Electric Storage Battery Company, certifying that the 10,000,000dols. capital is paid—"2,500dols in cash, and 9,997,500dols. in the purchase of patent rights necessary to carry on the business"!

Extending the Life.—In the use of incandescent lamps for train signals on the South Pacific Railway, which are highly successful, the electrician uses only half the lighting capacity of the lamps to replace the oil-lamps, and finds the life of the lamps extends to more than ten-fold by this usage, and the total cost is only one-third that of oil.

Wire Gauze Brushes.—By a slip of the printer, in our note of Mr. Crompton's wire gauze brushes last week, the word "gauze" was written "gauge." Those who did detect the error might read the note again. We believe these dynamo brushes, made out of wire gauze cut on the bias, will have an important place among the minor details of electric lighting.

New Electric Conductors.—A compound electric conductor has been patented in Vienna by Karcis and Bondy, consisting of two metals, a copper core and iron or steel wound spirally over this in the form of wire or thin ribbon. It is supposed to have superior advantages, being of great tenacity, low resistance, and without self-induction.

Electric Light on the Suez Canal.—Considerable trade is done on the Suez Canal by bringing out electric light plants for night use. Many of the ships have their own projectors, but those that are not so fitted are glad to use the projectors on hire, for the use of which they pay the sum of ten pounds. The apparatus is then used for a backward journey.

Oil on the Waters.—A new invention for oiling troubled waters consists in a rocket which can be fired before the ship even in a gale and discharges oil to smooth the water ahead. If electric launches ever, as they may soon, traverse open sea, they will have to be equipped with an electric squirt or rocket gun to smooth their onward way, and the troubles of sea-goers will be doubly overcome.

English Plant for America.—We learn that Messrs. Hammond and Co. are completing a large plant, on the Lowrie-Hall system, for a central electric lighting station in America. The Americans seem to think, by advices we hear of companies continually introducing their systems here, that we want teaching how to do central station lighting, and that they are just the people to do it. This item looks as if sometimes it was the other way round.

The Waterhouse System.—We learn that Messrs. Shippey Brothers, Limited, have been appointed agents to exploit this arc-light system for England, an illustration of which was given in our journal of June 1, 1888 (page 514). This company makes a speciality of 30, 50, 100, and 200 h.p. arc-light plants for provincial town lighting; and they guarantee to give ninety 1,700-c.p. lamps (nominally called 2,000 c.p.) for an actual expenditure of 50 horse-power.

Testing for Poor Connections.—It is sometimes necessary to determine the existence of a poor connection and to fix its position. Mr. A. Barrett, electrician-in-charge of the Kansas City installation, measures the circuit for resistance with a single cell, to test for this fault, and then with six or eight cells. If a poor connection exists the two measurements will vary considerably; if not there is no perceptible difference. This method has been found reliable and useful.

Corporation Lighting for Paris.—The Paris Corporation held on Friday night the closing sitting of its extraordinary session. It rejected two applications for a concession to light Paris by electricity, the contractors not having followed the specifications laid down by the Municipal Council, and voted a grant of £40,000 for the erection within the Halles Centrales of electric works for the supply by mains of the whole city. It is doubtful, however, whether the Government will allow the Corporation the exercise of such a monopoly.

The Magnetic Crane.—We recently described the application of very strong magnets for the purpose of lifting heavy pieces of pig iron. One peculiar point learned in connection with this magnetic substitute for the ordinary hooks used on cranes was that the magnet would attract the chain above equally well with the mass below, and lifting chains used on the crane were consequently entangled in the most puzzling snarl until ropes were substituted. It is quite possible that this apparatus affords an excellent

Digitized by Google

field for the brass chain made by the electric welding process of Professor Elihu Thomson.

Electric Light in Parks.—The application of arc lighting for the illumination of pleasure parks at night has been mooted for London. Baltimore, U.S., has tried the scheme and likes it. The electric lights which have been placed in Druid Hill Park were turned on last week for the first time, and the effect was fine. The lights extend from Madison-avenue entrance to the Mansion House, and placed at intervals of about 100 yards. The lights when turned on drew crowds of visitors to the park, who promenaded about enjoying the novelty of the occasion and also the beauty of the surroundings.

Hose Pipes in Electric Towers.—The city of St. Louis and other cities are investigating the merits of the tower system for electric wires, both for electric light wires and for the telephone and telegraph, now being developed at New Orleans, this system being preferred, among other reasons, because of the dampness of the soil. The second tower at New Orleans is now in course of erection. It is of attractive style, very light, and less obstructive to the view than ordinary electric towers, and is 150ft. in height. The authorities of New Orleans, in granting permission to construct the tower, stipulated that an iron pipe should be run up each tower, to be used in extinguishing fires, especially on the uneven and higher buildings, which cannot be reached by the fire-engines.

Testing Telephone Circuits.—Mr. Henry L. Bailey, electrician of the Bell Telephone Company of Missouri, says a peculiar feature of the exchange is that the entire system is tested every morning without "calling" a subscriber. The night chief makes the test of about 2,200 circuits in less than an hour, determining the condition of each circuit. A list of faults is laid on the day chief's desk, and he directs the inspectors, who report from telephone stations convenient to their residences, so that they remove the faults before they report at the office in the morning. As a rule the lines are cleared by 9 o'clock every morning. Mr. Bailey considers this exchange in many respects far in advance of anything he has ever seen.

A Comprehensive Central Station.—In Lynn, Massachusetts, is a central station which comprises a considerable variety of supply. The station has at present a capacity of 800 h.p., and was originally started for supplying electric light for the town along the shores at Beachmont. The new electric railway of the Boston and Lynn Company, to Crescent Beach, is now supplied by current from the station to the extent of 40 h.p., which will be increased by another 80 h.p. Thomson-Houston arc lights are being supplied from this station to the number of 125, shortly to be increased to 200. It is also running a 500 light incandescent alternate current dynamo, which in a short time will be doubled. This station, when complete, will be one of the largest and best equipped in New England.

New Brooms.—In the recent discussion on the electric light at the Bath Town Council a small joke was perpetrated between them by Mr. Cox and Alderman Gibbs. Mr. Cox, in opposing the subsidising of the company by the Corporation, mentioned the Thomson-Houston system, and alluded to it as a comparatively new system; he was told it was the perfection of electric lighting, but he must say it was a new broom, and probably swept clean at the commencement. Mr. Sturges denied it was an attempt at subsidy. Some persons, he said, no doubt objected to the proposal, and button-holed Mr. Cox about it, but that did not prove his unpopularity. As for the electric light being a new broom that swept clean, he never heard such nonsense. What connection was there between the electric light and a broom? Alderman Gibbs: There is the "Brush" system.

Paris Convocation.—At the Paris Exhibition of 1889 an international convocation of electricians will be called by the Société Internationale des Electriciens, to continue the work of the convocation at Paris of 1881. *L'Electricien* suggests the following questions to be settled: (1) To define and fix the practical units of power and energy derived from the C.G.S. system, *watt* and *joule*, in order to prevent the confusion which are continually encountered in recent works, even by the most esteemed authors; (2) To define and fix a *practical* photometric unit, the standard advocated by M. Violle not having been recognised by industrial circles; (3) To define and fix photometric measurements and the corresponding units, in order that the *uminous intensity* of a luminous point may not be confounded with the *quantity of light* and the *degree of lighting* produced by this point at a given position.

An Electric Bone Cutter.—Removal of sections of bone in surgical operations has heretofore been a long, tedious process, effected with a mallet, chisel, gouges, &c. It is, perhaps, the most brutal and unscientific method which could be adopted, and sounds like the operative butchery which existed in the last century. This has all been reformed by an invention called the electric osteotome, which is an instrument holding a circular saw at its extremity, revolved with lightning speed by an electric motor. This, when held against a bone, makes a clean cut through it in a few seconds; in fact, its action is instantaneous. By holding the osteotome in a slanting position, wedge-shaped pieces can be cut out with equal promptitude. There is no danger of the saw cutting the soft parts, as they are protected by a retractor, an instrument which is passed down and under the bone.

Ilfracombe Promenade to be Lighted.—At the special meeting of the Ilfracombe Local Board on Saturday, letters were read with reference to lighting the Victoria Parade. Messrs. Woodley, of London, offered to light the promenade with electricity, on an average of five hours a night, for £150 for the first year, provided the Board would pay £60 in the event of the fittings being taken away, and also offered to light the whole town with 272 lamps of 50 candle-power for £680 a year. The gas company offered to lay plant for lighting it with gas for about £180; the gas used would be about £50. Tenders were also received from Messrs. Sugg and Company and Mr. William Cole. It was resolved, after discussion, to accept Messrs. Woodley's terms for one year, the surveyor being asked to explain to them that the lamps would not be wanted for several months in the year. The surveyor was also instructed to ascertain the cost of similarly lighting the parade.

Hiring Out Motors.—A local paper at Newark, New Jersey, says: "The Daft Electric Company, which is the new applicant for favour in this city, will start a striking innovation, inasmuch as the motors instead of being sold outright will be rented to the consumers of power at a fixed sum per month, which will include the service of energy required and all necessary repairs which otherwise fall upon the purchasers of the motors and are considerable in the course of a year. The Daft Company is coming to

Digitized by Google

Newark, and will take offices at the headquarters of the Schuyler Electric Light Company. By this arrangement it will be possible to furnish power throughout a large circuit in the city for running fans, printing presses, elevators, sewing-machines and machinery of all kinds requiring from one-half to fifteen horse-power. If needed, electric lights can be put in to accompany the motors, and the lessee of the power can illuminate his place from the same source with slight additional cost."

Barnet.—The incandescent lamps for this station are to be 30 c.p. low-tension lamps run in series, with an automatic series fuse, and a switch for use if necessary. The lamps will be placed on ornamental lamp-posts, specially designed, 15ft. high, with reflector to throw the light down, and carrying an insulating shackle on the topmost point. Cable of 6,000 megohm resistance will be used for a certain distance each side of the shackle, and from these bare wire will connect to the next lamp. It is intended to use an independent steam-engine and dynamo to drive the street lighting, so as to be quite distinct from the private and shop lighting. The use of 30 c.p. lamps has proved itself successful in towns in America, distributed at the proper distances, and has in some cases replaced the tower system, by which a very strong arc light was erected at a great height to illuminate a whole district. The greater number of smaller lights insures a much more thorough illumination than could be obtained by the tower plan.

Electric Cars the Biggest Thing Out.—Mr. L. L. Lewis, of the Sacramento Electric Railway, is a great believer in electric cars. "Sacramento is going to have an electric railway," he says, "and it will be something of which the capital city will be proud. I have ordered cars from the Electric Car Company of America, whose immense works are at Philadelphia. I have a contract by which the first car, fully equipped, must be delived in Sacramento by July 1. It will be a sixteen-foot four-wheel car, with a storage battery of 8 h.p. The brakes, gongs, headlights—everything—are run by electricity. On Washington-avenue, in St. Louis; Fifth-avenue, New York, and in Philadelphia, I rode on electric railways, and they are the biggest thing out. The cars glide along without jolt or jar, and are under perfect control. The works in Philadelphia are unable to supply the demand for electric cars, and an addition for the exclusive manufacture of these cars is being made at a cost of over thirty thousand dollars."

Electrolytic Test Papers.—We have received from A. Wilke, electrician, of Berlin, a small booklet of test papers for ascertaining the poles of a cell, dynamo, or accumulator. These consist of a number of leaves of porous white material cut into five strips in each page which can readily be torn out, and then, moistened with the tongue or with water, they can be applied to the poles of the apparatus to be tested. On the current passing, the negative end turns red. The papers are put up in a very convenient form for use in the testing-room or laboratory, but we suppose it is hardly meant to be considered as a new invention. Faraday mentions an experiment of this nature in his works, and it has been a common usage among experimental electricians to take strips of ordinary white blotting paper moistened with a strong solution of iodide of potassium, which turns red at the negative pole. Messrs. Woodhouse and Rawson also utilise this action in their pole-tester, in which two knobs are immersed in such a solution, the negative knob taking a reddish tinge, which afterwards disappears. The little books of test papers of Herr Wilke will doubtless prove advantageous for purposes of this kind, and are put up in a very convenient manner.

Telegraphic Communication with Lighthouses. On Monday Sir G. Baden-Powell asked the First Lord of the Treasury whether, with a view to the better prevention of loss of life and property in cases of shipwreck, for the general advantage of the shipping and fishing industries, and for the more effectual defence of these realms in time of war, Her Majesty's Government would during the recess take into consideration the provision of a complete system of telegraphic communication between the postal telegraphs and all coastguard, lighthouse, lifeboat, and life-saving stations situated on the coast of the United Kingdom. Mr. W. H. Smith said, in answer, that with reference to the better prevention of loss of life and property at sea, I can only remind my hon. friend of the answer he received on April 16 last from my right hon. friend the President of the Board of Trade. In that answer it was stated that certain experiments must be continued for another 18 months, and, as that period has still many months to run, I am unable to give any further information on the subject. So far as regards the safety of this country, my hon. friend may rest assured that any measures which in the judgment of the Government are necessary for security will not be neglected by Her Majesty's Government.

Poole still keeps Gas.—At a meeting of the Poole Town Council, the Lighting Committee reported that, in consequence of the tenders having been referred back on account of some being irregular, considerable reductions had been obtained. The Poole Electric Light Company were only prepared to light the town proper with electricity, and, therefore, the committee could not recommend the adoption of that system at present. They had ascertained that the cost of lighting the town with electricity, and the outlying districts with oil, on a seven years' contract, would be £514. 7s. 6d. annually. The cost of lighting the borough with oil, on a three years' contract, would be as follows: With "Eclipse" burners, £470. 16s. 3d. annually; with "Empire" burners, £502. 4s. The cost of lighting with gas where available, and with oil where gas was not laid on, including £25 for supervision, on a three years' contract, would be £517. 10s. 2d. The committee, therefore, recommended the Council to accept the gas company's revised tender for gas at 3s. 6d. per 1,000 for three years. On the adjourned application of the Electric Light Company for permission to erect iron standards in different parts of the town for private lighting again coming before the Council, it was agreed to ask the company to submit drawings of the proposed posts.

Electric Tramcars Run by Gravity.—The following account from Columbus, Ohio, illustrates the possibility of working tramcars going up hill by the current generated by cars running down hill. Says a local paper: "An interesting sight was witnessed on the electric road last evening. As is well known, the track has a very steep grade between High-street and its eastern terminus. Last evening, as one of the cars was leaving the High-street end of the line, Prof. Short asked the engineer to stop the engine, which was done, thus shutting off the source of power. Still the car near High-street moved on up the grade without any apparent cause—without any power being delivered to it from the engine and dynamo, which were standing still. It was found on examination that a car near the east end of the line was coming down grade by its own volition, and at the same time furnishing the

Digitized by Google

power to pull the other one up a part of the way. In other words, the motion of the wheels caused the motor on the down-grade car to act as a dynamo and produce a current of electricity, which was immediately contributed to the other car. Prof. Short expected this result, but did not know to what extent; hence the test. Great are the wonders of electricity. This feature of the system is manifestly of great value, as every car coming down grade gives back the power which has been put into it to take it up the hill, and helps to bring the other car up grade."

New Companies.—It will be seen from the list of new companies that several important companies have recently been formed. The largest of these is the "Metropolitan," with half a million of capital to start with. The directorate of this company is a large and influential one, and the names are those of gentlemen who are well known as directors of other companies which have achieved an acknowledged success, and nothing succeeds like success. The "Chelsea" company has been successfully launched, and has obtained the capital required. Another company which will have little difficulty in finding favour with the public is that of "Crompton and Co." This differs from the preceding, in that it is really a manufacturing company. As a private concern we have been familiar with its work from the earliest efforts, and all those who have been engaged in electric lighting work will know that the industry owes a large part of its present position to the intense energy of Mr. Crompton and his partners, who, through good and evil report, have never failed to believe, and lead others to believe, in the future of the work. We heartily wish these new companies all possible success. They are born under different auspices to their predecessors, so many of whom came quickly to an end. Greater knowledge has been obtained as to the work to be performed, and in regard to the methods and the cost of carrying out such work.

The Schanschieff Battery Syndicate.—The state of inaction on the part of this company has, we are glad to say, now given way to one of activity, under revised conditions of work. The matter, we learn, has been adjusted as follows: The proceedings by which the original syndicate was being sent forward for winding up (having sold out to the Schanschieff Company) were able to be stopped in time, and this syndicate has been revived with a capital of £10,000. The paid-up £200,000 of the company has been returned nearly in full, that is to say, less an amount of about half-a-crown a share expended in advertising, the syndicate standing to about an equal loss. A part of the capital returned has been reinvested with the Syndicate to the extent mentioned, and the payment to the inventor is readjusted in a corresponding proportion. Besides this the inventor holds a considerable number of shares, and will, therefore, share in a more justifiable manner in the profits, when made, of the company. It is understood that the Syndicate have already entered into negotiations for the Australian patents for a sum already exceeding their capital, and the Italian rights are also in negotiation; besides which, they hold patents in sixteen other countries. The Syndicate intend to commence active business in England at once, and, as will be seen from their advertisement, are enquiring for a number of skilled electrical workmen.

Human Electricity.—In the *English Mechanic* for last week a sketch is given of an instrument invented some forty years ago by Mr. Rutter to indicate the electrical action generated in human and other bodies. It consists simply of a glass shade in which a single silk fibre suspends a pendulum bob of wax, swinging clear of a circular piece of glass on the bottom of the stand, which circle of glass covers a paper marked with concentric circles. The neck is suspended through a hole in the top of the shade, and is carried by a brass arm springing from an unlacquered knob on the wood stand, and all wood and metal is free from varnish. To use it, the right index finger is placed upon the knob, and sundry movements are said to result in the wax pendulum according to the state of health and sex of the operator, and being stronger when several operators are connected in series. It is well known that Prof. Crookes invented the radiometer while experimenting for traces of electrical or other similar action of the human body, and as the action of the nerves is probably electrical or akin to that action, the tracing of an inductive effect under proper circumstances might be expected, and possibly even the effects of free electricity or magnetism, of either the usual or a more occult kind, might be perceived. We are not aware that anything really scientific has ever come of these experiments, but perhaps some of our readers may have heard of such experiments being performed with some definite result.

High Candle-Power Incandescent Lamps.—At the convention of patent experts recent held at Washington, U.S.A., appointed by the trade in order to discuss the validity of certain claims in dispute in connection with and relating to incandescent lamp manufacture, the award has been given to Shippey Brothers, Limited, of London, as assignees and sole owners of the Zanni-Shippey patents, No. 5,955 of 1883, and No. 11,802 of 1887, which combined patents are the only ones which describe a system for making high c.p. lamps for incandescent electric lighting. The assembly based their decision and report upon the following facts—viz.: That the inventions of Thomas Alva Edison clearly specifies that the object sought to be obtained by him was the production of an electric lamp of 16 c.p., with a view, as stated in the specification, to replace the ordinary gas-burner used at the date of the said invention, as the standard of light then adopted for commercial purposes. Whereas the invention of Messrs. Zanni-Shippey, which is clearly shown by the descriptive matter set forth and explained in the specifications, had also a special object in view — viz., that of producing an incandescent light burning in vacuo, of increased illumination and high c.p. as mentioned of 100 c.p. and upwards, described and printed in the patent specification. For comparison and as an analogy, the convention took as the basis of argument the ordinary commercial gas-burner and the Wenham lights, both of which systems of lighting had their special sphere and objects in view, as and for the purposes named, but covered under different inventions of a similar nature. The assembly also gave a certificate as to priority of invention for fancy striped and coloured lamps for decorative lighting to Messrs. Zanni-Shippey, for certain special designs explained by the drawings as affixed to the British, French, and Belgium specifications. This award is an important one, and by the recent decision of Mr. Justice Kay as to the validity of certain lamp patents it opens up a question respecting fancy lamps and for all lamps of 100 c.p. and upwards for incandescent lighting. Messrs. Shippey Brothers, Limited, announce that they do not intend to manufacture lamps, but will maintain their rights held under these patents; and in order to prevent

Digitized by Google

complication and annoyance to users, they are prepared to grant licenses to manufacturers to make and supply same on reasonable terms of royalty.

Telegraphing to Trains.—At the meeting of the Railway Telegraph Superintendents, New York, on July 11, Mr. J. W. Lattig, on behalf of the Lehigh Valley Railroad, invited the association to take a trip to Easton over that line and inspect the working of the train telegraph in practical use. Mr. Lattig said that during the blizzard last March, it was their only reliance for telegraphic communication for three days. All the relief and supply trains were governed through the medium of the train telegraph, and its operators were on duty night and day. A serious accident occurred at this time, and there was no other means of communicating with the wreck. The wire was broken once on Monday at Bound Brook by other wires falling upon it. Their experience had been that this system works better in stormy than in dry weather. The use of it for commercial telegraphing was gradually increasing. None of the previously existing telegraph offices had been abandoned by reason of its introduction, because the growth of business on the road required constantly increasing facilities. A gravel-train had been equipped with the apparatus, which was engaged in the construction of an additional track. One hundred men were employed on this train, and during the first week one hour and forty minutes of time was saved by the train obtaining permission to remain on the main line. Working time for this train had been saved every week since it was fitted up and provided with means of constant communication with the dispatcher's office. All of the wrecking trains have now been equipped with these instruments, so that after being ordered out they are in communication with headquarters until the wreck is cleared away and the train returns. The guests were taken in a special car fitted up with the induction train telegraph apparatus for a trip over the Lehigh Valley road attached to the regular train. Mr. J. W. Lattig (who is superintendent of the Lehigh Valley road) took charge of the party, and an opportunity was given to the visitors to test the merits of the train telegraph. The length of time it has now been in use leaves no doubt as to its practical utility, not so much for the convenience of travellers as for constant use in the administration of the affairs of the company. Although the perfect reading of the signals is somewhat difficult at the outset to an operator not familiar with the sound, those who have had very little experience with the instruments have no trouble in copying long communications as readily as with the ordinary Morse apparatus. The exhibition was highly satisfactory, and gave a very good impression of the value of the system. We notice with pleasure the attention this method of communication is receiving from the railway telegraph-engineers in America. We think it is about time that a convention for the investigation of experiments of telegraphing to trains in motion was brought about among the railway telegraph-engineers of this country. These enterprising gentlemen are surely not going to let an important and time-saving invention drop out of sight for want of a little enterprise, but we are yet waiting to hear of the first application of the discovery in England.

Automatic Railway Signals.—The Pennsylvania Steel Company exhibited, at the recent meeting at New York of the Railway Telegraph Superintendents, a magneto-electric alarm signal for highway crossings, a hand semaphore signal, and a block system, which is the result and, in a measure, a combination of the other two. The distinguishing feature of all these appliances is that the electric current is generated from the power of the train by a dynamo of the magneto type, giving an alternating current and avoiding the use of cup batteries, which need a great deal of attention and are especially liable to get out of order by freezing. The generator or dynamo consists of from six to 12 large permanent steel magnets mounted in a strong frame, with a Siemens armature between the poles of these magnets. This armature by the undermentioned arrangement is made to rotate by passing trains, and thus an alternating current of considerable power is generated. Each wheel which has a tread wider than the rail, depresses a lever placed parallel and close to the rail and projecting above it from $\frac{1}{16}$ to $\frac{1}{4}$in. The motion of the lever compresses two strong spiral springs, and when the wheel has passed off the lever, these springs are released, and by means of a ratchet wheel an impulse is given to the armature shaft. This ratchet was designed especially for this machine, the motion being transmitted by a perfectly positive clutch for forward motion, and backward motion being accompanied by no noise and very little friction. A fly wheel gives steadiness and continuity to the motion derived from the impulses given by the passing wheels. A water-tight iron box, 16in. square and 13in. high, encloses the mechanism, and is placed far enough from the track to be out of the way of snow ploughs, &c. The armature shaft connects with the steel lever beside the rail. The same kind of dynamo is used for the highway alarm and the block system, and one of similar design, but operated by turning a crank, for the hand semaphore. There are no brushes or commutators to get out of order, and no batteries requiring renewal. The current thus generated can be transmitted any moderate distance, say up to six or eight miles, and there used to sound an alarm gong or operate a semaphore. A vibrating armature permits the use of the alternating current, which is one of the distinguishing peculiarities of this system. The motor and a semaphore or alarm gong are mounted on a post 16ft. to 20ft. high. The equipment for a crossing consists of two dynamos, usually placed from 1,500ft. to 1,800ft. from the crossing, and two posts, two motors and two bells, the whole costing less than £70. For use on single track roads a second lever is placed beside the rail, nearer the crossing than the first one, so that when a train is moving *from* the crossing this level will be depressed first, a switch turned, and no alarm sounded. The passage of a single wheel is sufficient to start the alarm, and after the passage of a train it continues to ring for some time, generally until the train reaches the crossing. In the block system the passage of a train throws up the danger signal at that point, and immediately afterwards throws down the danger signal at the preceding station, which may be several miles back. Thus, in no case can two trains get upon the same section if the signals are observed, for the warning cannot be removed at the beginning of one section until the train has passed on to the next one. One dynamo, and one motor, and semaphore will be required for each section. The cost will depend upon the length of section adopted. The semaphores can be so adjusted that an enormous force would be required to change their position by other means than that intended. This system has just been brought before the public, and is not yet in operation, but seems to be an important advance in automatic railway signalling.

NOTES ON DYNAMO CONSTRUCTION.

BY SYDNEY F. WALKER.

(Concluded from page 73.)

Next, having decided upon the form of the armature, shall it be built of wire or discs, and how shall it be driven? It must be borne in mind that it is the wire on the armature which has to be driven. If that can be accomplished with good lasting results, mechanically, the core may be left to take care of itself, but the most efficient method of driving the wire through the magnetic field is by causing the core to rotate, and attaching the wire more or less rigidly to it; so that the first part of the problem is, after all, to drive the core. Some makers have taken a great fancy to iron discs fixed direct to the spindle, either strung on centrally, as in the Edison-Hopkinson, or dove-tailed on, as in the Crompton. There can be no doubt that mechanically such an arrangement is very efficient; but electrically, in the writer's opinion, it is not so. The remarks that were made with reference to Pacinotti discs apply here, though in a less degree. In the first place the Faucault currents are not so perfectly neutralised; or, to put it more correctly, the path of the Faucault currents, is not of so high a resistance as with the iron wire—with the latter, lamination is carried out in all directions. The E.M.F. at the periphery of the disc is higher than on the inside, and we know, in such cases, the current finds paths for itself within the disc. Further, one side of the circuit is by this means placed in conductive connection with the spindle and the body of the machine. So long as the insulation of the other parts of the machine remains perfect, and the E.M.F. low, this is not a serious matter; but if the insulation of any other part is defective, you have a leakage circuit open at once that will probably lead to burning of the bobbin, or part of it. Further, where high E.M.F.'s are used, this arrangement adds considerably to the danger to life from their use. There is only the cotton or silk covering of the wire, and whatever insulation may be used on the core between the one side of the machine and ground. Given a high tension machine, a man whose clothes are wet, on a wet night, standing on the ground, or even on a wet ladder, some distance down the circuit; the man with his naked hand, or a wet gloved hand, on some part of the conductor; and at the same time some change in the circuit, such as one or two arc lamps being turned in or out, and you have all the conditions for a very severe shock. The problem of the insulation of the machine from ground is one of the most important that will have to be considered when the question of transmission of power comes up for solution practically; and it becomes necessary to place high tension apparatus in unskilled hands.

Then as to driving. With ring armatures, if wire is used for the core; notwithstanding all that has been said against the old wood hub, properly constructed, and especially for bobbins of large diameter, it is by no means such a bad mechanical contrivance as it is made out; and, on the other hand, it lends itself to perfect insulation. Where, however, the bobbin is small in size and has much work to do, the wood hub is unreliable, as it is difficult to obtain sufficient grip. There is also some difficulty in obtaining wood properly seasoned and that will stand. The only resource is therefore to fall back on some form of spider to hold the core. In the Elwell-Parker machines, originally, brass bosses were driven into the spindle, carrying arms; and on these arms the core was wound, vulcanised fibre being placed between the core and the arm. The great objection to this was that the fibre had to drive, or at least to transmit the power. Vulcanised fibre is a substance that is subject to great changes. When dry, for instance, it is a fair insulator; when wet a bad one; and it also appears to undergo great changes in the presence of heat or electric currents, so that after a time it will lose many of its properties. This being so, it might be expected that the fibre would gradually give way, and as Messrs. Elwell-Parker have recently given up this plan, it may be supposed that some reasoning of the kind has held with them. Another plan is that of Mr. Kapp. It is a most significant fact that Mr. Kapp should revert to the wire core after having had full opportunities of knowing the advantages of the stamped disc system.

Mr. Kapp has worked out at some pains a special form of carriage for his core, which also includes an arrangement of horns for driving the wire in a positive manner. It is very doubtful, in the writer's opinion, if much is gained by this plan, while it adds considerably to the expense of construction. Further, should the core be saturated sufficiently to allow of lines of force passing through the centre, this carriage would become a source of loss by reason of the currents developed in it. Messrs. Crompton's method of dove-tailing their discs on to the spindle and the method adopted of stringing the discs of the Edison-Hopkinson machine, have already been mentioned. For drum cores generally there are many very good plans of driving, such as having two discs keyed on the spindle, one at each end of the core, and filling the space with wire. The plan adopted by Messrs. Paterson and Cooper for driving their Pacinotti bobbin is to string their iron discs together by three bolts, insulated from the core, and secured rigidly at each end to a stout disc or spider keyed on the spindle. This plan is better electrically than those generally adopted with discs, but is not so good mechanically, although it is only fair to say that it appears to work very well. Electrically, it is open to the objection that the wrapping or other insulation on the bolts is very liable to be worn through, and the core is then in connection with the body of the machine.

The methods of driving disc armatures have been indicated. The advantages and disadvantages of each form of dynamo—viz., single or double horse-shoe armature—parallel or at right angles to plane of field magnets have also been discussed; but a few words more on the multipolar dynamo may be of service. The principal objection to the multipolar dynamo lies, in the writer's opinion, in the increased expense of construction. There are so many parts, all of which require to be carefully fitted together. The connections between the armature and commutator are very much more troublesome to make, and therefore more expensive; there may be also two or more sets of brush-holders, and the magnetic resistance, as constructed by those who have adopted this plan, is apparently higher than that of other types. Further than this, the four-pole machines at present in the market, though they do their work well, do not, with the exception of that of Messrs. Elwell-Parker, appear to be mechanically as strong as other types.

Another point that appears to be worth discussing is, should the magnet bars of dynamos generally be solid or laminated? The writer observes that Mr. Fricker, in the course of his able series of papers on this subject, recommends the latter. On that point the writer would differ from him, and for purely mechanical reasons. He believes from what he has seen that the gain from the dissipation of heat is more than neutralised by the loss of mechanical strength and the increase of the magnetic resistance.

These notes would hardly be complete without some reference to the iron clad dynamo as it has been called. Its *raison d'ête* is as follows: When a current of electricity passes through a wire, we know that it creates lines of force which take the form of concentric circles round the wire. That is to say, any free magnet of small size brought into the neighbourhood of such a wire will place itself as a tangent to one of these circles. The result of this action upon a bar, or a ring of iron, or a series of magnetic conductors, such as rule in the ordinary dynamo, is to set up a continuous magnetic circuit in the iron and the space within which the wire on the armature revolves. Now, as we know, for any speed and number of turns, the E.M.F. generated in a given dynamo depends directly upon the number of lines passing across the space in which the wire moves, and this depends upon the exciting power divided by the magnet resistance. One part of this resistance is that of the magnet limbs, yoke, pole-pieces, &c., and the fact of our having to force the magnetic current through them, makes a charge upon the exciting power, and reduces the efficiency of the machine. If we can eliminate this resistance, we reduce this charge and increase the efficiency of

Digitized by Google

the machine, and we may also, it is thought, reduce the magnetic leakage. The plan proposed is, in place of wrapping the exciting wire of the field-magnets upon bars of iron, and causing them to conduct the lines of force to the armature, to wrap the exciting wire directly round the armature, so that the magnetic circuit is composed only of the exciting wire, the air space, the revolving conductor, and the armature core. Now the question arises, can this be done economically, and what is hoped to be gained by it? It must not be forgotten that the iron bars round which the wire is wrapped perform two offices; they not only conduct the magnetism, but they form a portion, and often an important portion, of the framework of the machine. If we can magnetise our armature directly without giving rise to other sources of loss, and at the same time construct our machine as strongly and as cheaply in other respects, we shall gain not only in efficiency, but in the cost of the wire required to excite the field-magnets. In the writer's opinion, however, this is by no means easy of accomplishment.

THE CHARGE ON THE ATOM.

BY J. ENRIGHT, B.Sc., LOND.

According to the doctrine of Helmholtz, as expounded in the Faraday Lecture of 1881, each atom in a compound is attached to a definite quantity of electricity. The atom of iodine, for instance, in argentic iodide is attached to a definite quantity of negative electricity, and the atom of silver to an equal quantity of positive electricity. The atoms forming the molecule are cemented together by these opposite charges. When the attraction between the charges is overcome, the molecule is destroyed, and the elements are set free. Electricity is thus placed in an all-important and all-pervading position in Nature. It is an essential of the molecule—that is to say, of matter.

An unsuccessful experimental search for some evidence of the existence of these charges, together with the failure of the theory to account for ordinary chemical facts, constrain one to harbour serious doubts with regard to it. The basis of the doctrine is Faraday's "Laws of Electrolysis"; but even did it give a satisfactory explanation of the facts of electro-decomposition it could scarcely be considered ground enough for a theory of such scope and importance to rest upon, and I believe that as the subject comes to be more studied, the haste with which it was accepted will appear surprising. At the close of Helmholtz's famous discourse no less an authority than Sir H. Roscoe, the then President of the Chemical Society, gave it official sanction, and from that night to the present day "the charge on the atom" has been almost universally assumed. Nevertheless, scarcely any attempt has since been made to show how the common facts of chemistry, such as double decomposition and displacement, are explained by, or harmonise with, the theory. Neither has anybody, as far as I can ascertain, even discussed the weighty objections raised against it by Maxwell. It is proposed in this paper to fairly confront it with well-known facts and to give the results of experiments made with the expectation of elucidating it. The subject is inseparably connected with the theory of "dissociation," and the bearing of the one on the other will have to be treated.

It is established beyond doubt that when a current of electricity of sufficient strength is passed through an electrolyte, such as a solution of $CuSo_4$ in water, not only are the ions liberated at the electrodes but that there is an actual translation of them through the liquid. The exact mode of transference is still under discussion. The "orthodox," sticking to the theory of Clausius, teach that the molecules of liquids are in perpetual motion, and that the consequent encounters between them are so violent and jarring as to wreck some of them, setting free the constituent atoms or radicals, which nevertheless retain the charges with which Helmholtz has endowed them. The smallest current passing through such a liquid suffices to move anions to one electrode and cations to the other, but their actual ejection from the electrolyte does not occur until an E.M.F. of definite quantity is applied to it. Further, the wandering ions of Clausius are the only means by which quantities of electricity are conducted from one electrode to the other.

With regard to the theory of dissociation, it appears to me that a good deal of information may be obtained from a consideration of certain well-known reactions in which precipitates appear only after the lapse of time. For instance, dilute solutions of H_2SO_4 and $SrCl_2$ react, but precipitation does not occur until after an interval of six or ten minutes. Many other similar instances of slow precipitation are well known. Mr. Crooks has recently given instances of precipitation not taking place for hours after mixing the reacting solutions. I consider such facts at once an argument against the dissociation theory. A mixture of dilute solutions of strontic chloride and hydric sulphate is an electrolyte, and conducts well. A couple of Daniell's cells liberates gas freely from it; and therefore, according to theory, a host of wandering ions traverse it irregularly when a current is not passing through it. The ions are in two sets, oppositely charged. The members of each set repel one another, while the members of both sets are mutually attractive. Under such favourable circumstances for the encounter of the oppositely-charged ions, composing $SrSO_4$, it is very difficult to see why precipitation should not take place before so great an interval as six or ten minutes. When solutions of strontic chloride and hydric sulphate are concentrated, it is true that precipitation takes place far more rapidly; and it may be urged by supporters of "dissociation" that, after all, the facts are strongly in their favour, since with more concentrated solutions, and, therefore, presumably with a greater number of wandering atoms, the chances of encounter between the ions of $Sr\,SO_4$ are increased and precipitation accelerated.

As already indicated, the fact that a mixture of the dilute solutions conducts well disposes of this objection; but this is not all. The experiments of Kohlraush, Ostwold, and others prove that the conductivity of salts in solution increases with dilution. The "orthodox" are bound to interpret this as asserting that a greater number of wandering ions exist in dilute than in more concentrated solutions, from which it follows that precipitation ought to take place more quickly in the former. But the reverse is the fact.

The basis of this argument against the dissociation theory must be admitted by its supporters, for the experiment by which Prof. Lodge proved the actual transference of the ions through an electrolyte by the influence of the galvanic current must have been planned with the belief that oppositely-charged free ions moving about through a liquid do not fail to combine and form molecules. The experiment is described in the Aberdeen British Association report. One electrode and a solution of $BaCl_2$ were placed in one vessel, the other electrode and a solution of Na_2SO_4 were placed in a second vessel. Both vessels were connected by a long tube containing dilute HCl. and a current passed. After an interval of time a ring of $BaSO_4$ was formed at a considerable distance from either vessel in the connecting tube. I shall refer to this experiment for another purpose later.

Let us assume in favour of the supporters of "dissociation," that the slowness of precipitation from a mixture of solutions of $SrCl_2$, and H_2SO_4 is due to mere paucity in the number of free rambling ions traversing this particular liquid. What upon this ground will be the effect of passing a current through such a mixture during the period of apparent reaction before precipitation? When this experiment first occurred to me as likely to throw light on these matters, I reasoned as follows: There are two ways of figuring in one's mind the posture of affairs among the molecules of the mixture during the period of apparent inaction.

(1) The ions are straining—pulling or twisting—at one another. The forces in action are not very unequal, or the process being performed is a slow one—similar, it may be, to unscrewing. At all events the existing molecules of $SrCl_2$ and H_2SO_4 are in course of demolition in order to form the new molecules of $SrSO_4$ and HCl. If this be the real state of affairs and if the passage of a current through an electrolyte tends to break up its molecules, then I thought passing a current through the mixture during the period of apparent inaction should hasten precipitation.

(2) Through the mixture, according to the dissociation

Digitized by Google

theory, a rather small number of free ions carrying the charges of Helmholtz are careering, and although the ions composing the $SrSO_4$ would eagerly combine at an encounter, such an event does not occur on account of their sparseness. If this be the real state of affairs, and if the passage of a current through an electrolyte tends to sweep the anions to one side, and the cations to the other, then I thought passing a current through the mixture as before should lessen the chances of encounter between the ions composing the $SrSO_4$, and so retard precipitation.

Here I had something in the nature of an *experimentum crucis*. Dilute solutions of H_2SO_4 and $SrCl_2$ were accordingly prepared. The concentration was such as to ensure precipitation in about six or seven minutes from the time of mixing. Equal portions of the solutions were mixed in a beaker, and equal portions of the mixture were placed in two smaller beakers of equal diameter. A current from five Bunsen's cells was passed through one portion of the mixture by means of platinum electrodes. A precipitate appeared in this in about three minutes. A trace of turbidity appeared in its counterpart in four minutes; but, for several minutes after, the greater quantity of deposit in the part through which the current passed was perceptible. I made similar experiments with solutions of nitre and tartaric acid, and a few other such mixtures, with confirmation of the result just mentioned.

I communicated the results of these experiments to Dr. Gladstone, and in the course of conversation he informed me that although they were not published up to that time he made the same experiments, but with a totally different object, many years before, and he read a paper on the subject at the British Association meeting of last year. The fact of the acceleration of precipitation is thus placed beyond question, and I submit that the dissociation theory and the Helmholtz theory cannot *both* stand in face of it. The precipitation of $SrSO_4$ from dilute solutions of H_2SO_4 and $SrCl_2$ is also hastened by heating or agitation, but as far as I can judge the arguments that may be grounded on these facts weigh pretty evenly on both sides. There remains to be considered, however, whether the heating effect of the current is not the cause of the more rapid precipitation which we have attributed to the current as such. I have made numerous experiments to clear up this point, and find that in all cases there is something standing to the credit of the current, apart from the rise of temperature it produces. I shall describe one which I consider decisive.

Equal volumes of rather strong solutions of tartaric acid and nitre were placed in a beaker and mixed. The mixture was divided into two equal parts, through one of which a current from five Bunsen's cells was passed for four minutes. The other was placed in a sand bath, and kept at a temperature of 48deg. C. for five minutes. The temperature of the first was raised from 9deg. C. to 21deg. C. during the four minutes the current passed through it. A comparison of the beakers left no doubt on the point. The deposit from the portion of the mixture through which the current passed was much greater than from its counterpart, although the temperature of the latter was 48deg. C., while that of the former did not rise higher than 21deg. C.

It appears to me that Helmholtz studiously avoided any reference to the dissociation theory throughout the Faraday Lecture, and, without being strong on the point, I feel that he is at variance—at least, as far as he expresses himself in his famous discourse—with the most "orthodox" authority on the subject. I gather, from the passages I am about to quote, that Helmholtz conceded to the electric strain the power of breaking up the molecule. He is arguing that there exists only the electric forces to bind the ions into the molecule, and says: "We must conclude, therefore, that no other force resists the motions of the ions through the interior of the liquid than the mutual attractions of their electric charges." Now, these "mutual attractions" are precisely what, according to Helmholtz, keep the molecules intact. Again, he says, "Even the feeble electric tension of two Daniell's elements acting through an electrolytic cell upon the enormous quantities of electricity with which the constituent ions of water are charged is mighty enough to separate these elements and keep them separated," And again, "At the surface of the electrodes decomposition can take place if there is sufficient electromotive power, and then the atoms can give off their electric charges and become electrically neutral." (Abstract of the Faraday Lecture, prepared by the author. "Nature," April 7, 1881. All quotations given from the lecture are from the same source.)

I cannot help contrasting this position with that taken up by Prof. Lodge: "All that a slope of polentia can possibly achieve in the interior of an electrolyte is to direct the procession of otherwise randomly moving atoms. This is, of course, the foundation of the theory of Williamson and Clausius, and all experimental knowledge acquired since the time it was first promulgated, with regard to the obedience of electrolytes to Ohm's law down to the research of Prof. Fitzgerald and Mr. Trouton, communicated in part to the last British Association, and still going on, tends but to confirm and strengthen the position."

Notwithstanding this disagreement with Helmholtz, Prof. Lodge stands fast by "the charge on the atom," and it appears a trifle inconsistent, if one may say so, of so high an authority to hold that the charged ions are driven unerringly in definite directions for great distances by the action of the current, while the same current is quite unable to affect the same charged ions when they compose a molecule. At all events, the current ought to cause the molecules to turn round and lie with the positively charged ions towards the positive electrode, and the negatively charged ions towards the negative, after the manner of a compass needle in a magnetic field. But if the current be vouchsafed this power, a tendency to break up the molecule is conceded to it, for the friction between itself and adjacent molecules during rotation would tend to tear the constituent ions apart.

Again, one is tempted to remark that it is not quite apparent how obedience to Ohm's law on the part of an electrolyte gives any ground for a belief in the theory of "dissociation." The resistance of an electrolyte may vary very irregularly, or behave in a different manner to metallic conductors, as varying currents are passed through it, and yet conform to the equation $C = \frac{E}{R}$ at every phase. If "dissociation" be a fact, the strength of the current must affect the resistance of electrolytes in another way besides altering the temperature. In fact, the quantity current must enter into the expression giving the resistance of a particular electrolyte under a given set of conditions. And were it proved that an electrolyte permitted the current to increase regularly as increments of E.M.F. were switched into an external circuit of comparatively low resistance through a certain range of difference of potential, but that at a definite value of current it stopped dead, and became for all further increments of E.M.F. as bad a conductor as turpentine, I should then begin to believe in "dissociation," for such, according to the theory, should be its behaviour, as I now proceed to show. The conductuity of a liquid has been proved to depend upon temperature and dilution, and it is not unlikely that other circumstances as well control this property. Every electrolyte, therefore, must be assumed by supporters of "dissociation" to have for *specified conditions* a definite rate—"a constant average of 'dissociation'"—at which free rambling ions get into it. For a particular electrolyte this rate is the limit of the rate at which electricity can pass across between the electrodes. Let us suppose this limit to be reached by choosing a current of suitable strength. We have now a steady flow of ions carrying across all the electricity brought to the electrodes by the leads. Every available free ion is occupied, and there is no provision for reinforcement, because, as we are taught, the current has not the power of dissociating. Neither can the quantity carried by each ion be altered, for that, according to Helmholtz, is fixed by the atomicity. If, under these conditions, the E.M.F. in the external circuit be increased, what is to occur? The current cannot possibly increase; so that, according to theory, it might very well have happened in the course of experiments on the resistance of electrolytes that a current was found in some cases to increase regularly as E.M.F. was added up to a certain limit, but that on this limit being reached, no further

Digitized by Google

increase of E.M.F. could cause an increase of current. I have seen no account of such a phenomenon.

(To be continued.)

NEW MAGNETO BELLS.

The introduction of magneto-electric bells is of considerable advantage in many instances, as it obviates the use of a battery, with its many possibilities of getting out of order.

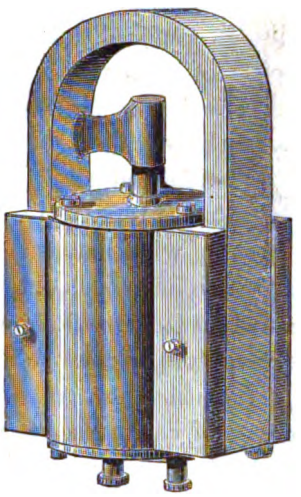

FIG. 1.

Several forms of magneto bells have been tried, but none seem to have met with much success. The new form

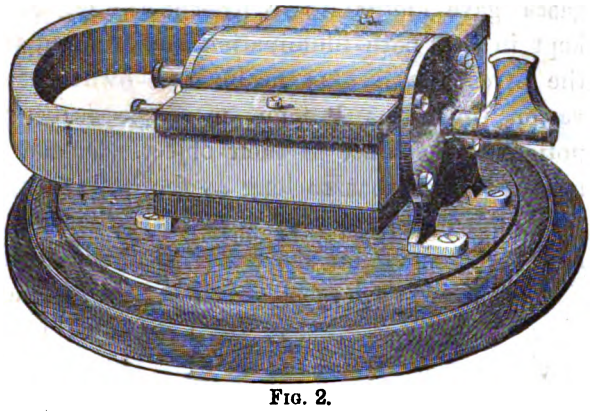

FIG. 2.

designed by Messrs. E. Cox-Walker and A. A. Campbell Swinton possesses features of interest, and well fulfils the

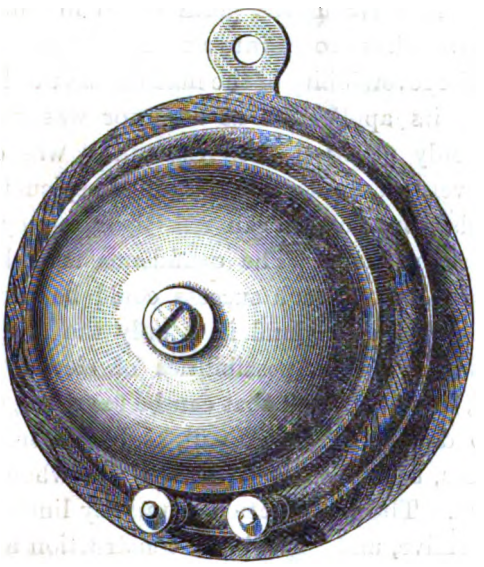

FIG. 3.

functions for which it is intended. Two forms of the generator as shown in Figs. 1 and 2, the former a fixed, the latter a portable form. It consists of a Siemens' armature working between the poles of a permanent magnet. The armature is worked by a thumb piece, and is so arranged as to have only a backward and forward movement, about a quarter of a turn each way. The current thus generated is sufficient to actuate the bell through some 500 ohms resistance. The bell can, as usual, be had of various forms. Fig. 3 shows a self-contained portable form. The core of the electro-magnet of these bells is polarised by means of a small permanent magnet, and the

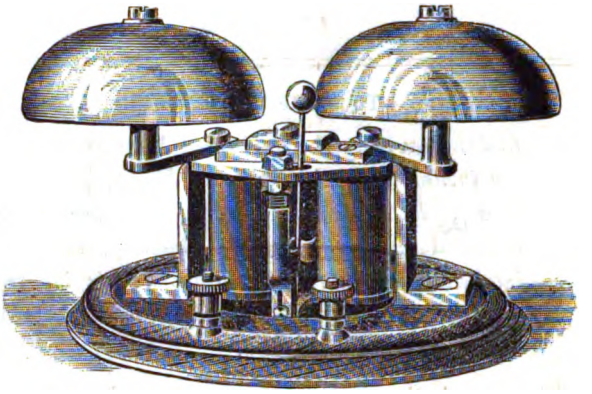

FIG. 4.

hammer strikes upon two slight prolongations of the gong rim, between which it vibrates. Fig. 4 shows a form with double gongs.

CORRESPONDENCE.

"NOTES ON DYNAMO CONSTRUCTION."

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—I have read with much interest Mr. S. F. Walker's papers on the construction of dynamos, but I think it will be in the interest of your readers if I correct a statement made by Mr Walker respecting the construction of the armature of the Gülcher dynamo.

The wooden centre, with charcoal plates on each side, with discs for gripping the ring and securing it to the spindle, has been discarded for nearly five years, because we found that:

Firstly. It was most unmechanical, as the armature slipped.

Secondly. It was most inefficient, as eddy currents were generated in the iron plates.

Thirdly. It was impossible to repair the armature without taking the whole machine to pieces and breaking every connection to the commutator.

Our first alteration was to make a gun-metal pulley with a central rib. Upon the gun-metal pulley we wound charcoal iron ribbon up to the full diameter of the central rib, and then turned off the top portion to a semi-circular form, so that there was no flat surface presented to the top of the pole-piece. This entirely prevented heating, and made the armature extremely strong and readily repaired in case of accident.

We have now abolished this plan, and wind the same pulley casting with charcoal iron wire, until the section of the armature core is square. In the small machines up to 20 unit the central gun metal rib is dispensed with, but in the larger machines the central rib has a number of slots cut in its periphery which hold the wire, and at the same time add extreme strength to the construction. Of course, the iron wire is wound on under a heavy tension, and we never find the slightest difficulty of any kind. We have no trouble from heating of the core, and the latest tests of our four-pole dynamos give 1 volt for every seven inches of active wire on the armature, the total amount of active wire being 56 per cent. This result is obtained at a mean periphery speed of 3,300ft. per minute.

I need hardly say that it will afford me much pleasure to show Mr. Walker one of our modern machines, when I have no doubt he will form a different impression respecting multipolar dynamos.—Yours faithfully,

M. MOUNTAIN, General Manager.

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, ESQ., *President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of* W. H. WOLLASTON, M.D., F.R.S., *and on April 20th we gave that of* SIR HUMPHRY DAVY, F.R.S., *whose fame as an electrician is still more prominent than that of* WOLLASTON. *Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of* PROF. D. E. HUGHES, F.R.S.

TRAMWAYS.

The lengthy paper of Mr. Sprague read before the American Institute of Electrical Engineers, given elsewhere in our columns, again directs attention to a topic of the utmost importance. It is often said that Englishmen are apt to stand aside and allow others to prove the utility of a new invention or suggestion, then having seen it proved, we take it in hand and generally improve somewhat upon the original. This is especially the case when the original is a piece of mechanical apparatus. In the question of electrical traction the Englishman has not been particularly eager, but has been quite willing to stand aside and let his American cousin test to his heart's content. Mr. Sprague's paper tells us something of what has been done in America and the results which have been obtained. An investigation in the Patent Office will show that among the earliest ideas inventors had as to the application of electricity was its utilisation in some way or other for the propulsion of carriages. Some of the earlier inventors, as Pinkus, designed pneumatic systems wherein electricity was employed as an auxiliary, others, as Talbot, generated mixed gases by means of an electric current, and then by exploding the gases gave motion to a fly-wheel. De Moleyns kept in view both illumination and motion, and as the investigation gets nearer our own times the various inventors become more precise in their notions and definite in their object. Of course we now recognise that so long as the battery was the best known generator of electricity, there was no hope for its commercial success to obtain illumination or motive power. After all is said and done—after we have credited all who designed magneto machines or dynamos, the time had not come when these things were possible till Gramme produced his machine. From the initiative of Gramme the era denoting the modern progress of electricity takes its date. He gave us the germ which in the hands of improvers has grown into a colossal commercial tree. But the reversibility of the machine had to be noticed before its application as a motor was recognised. The only question then remaining was cost, and here venturesomeness was not conspicuous. Anyone else, but not us, can risk their money to prove success or failure. The confidence trick had to be repeated before such success could be proved, and even now in England it is only the few who are convinced of the possibilities of electric traction. That, however, is all that can be expected, and there is no doubt the leaven will, as heretofore in other matters, be sufficient to leaven the whole lump of inertia. The construction of railway lines has been progressive, and so will the construction and equipment of electric lines. Not long since we referred to a syndicate endeavouring to, or rather claiming to, control series working. We believe that quietly

Digitized by Google

the whole of the English and American patents claiming anything in this direction have been obtained, and now belong to the syndicate, and, according to the prospectus, it is proposed to form a company in a month or two in order to exploit the series system in England. Again, it is rumoured that so far as the electrical arrangements are concerned, there is nothing to prevent the long-talked-of experiment upon the Metropolitan Railway, delay being caused solely by conflicting interests. Further, a contract has been, or is about to be, signed for the equipment by an English firm of a line of some twenty miles, while other firms are carrying out what may be termed exhaustive experiments for the information of tramway companies. It would be easy to describe an ideal town where electricity was a kind of universal provider—where, by its means, motive power was distributed in warehouse and street, where illumination came from a similar source, where neither horse nor mule had home or were required for labour. One advantage under these circumstances would arise in the simplification of street sanitation, and a great saving would accrue in the wear and tear of the streets. Mr. Sprague and others may labour to prove the direct saving that will come by the general use of electricity in traction, but we would also point out that the indirect saving is likely to be far greater than the direct, and the latter is an influence that may be brought to bear upon every household and ratepayer, while the former appeals rather to the pockets of the shareholder than to the community at large. If in a district the normal number of horses using the streets is, say, five thousand, and these be reduced one-half by the use of electricity, then the wear and tear due to the tramping of these horses is saved, and it is no stretch of the imagination to say the life of the streets is doubled, while the cost for cleansing the streets is reduced. Unfortunately, few people consider these indirect advantages. Most of us only understand direct advantages, and anything that puts a shilling into our pockets is appreciated, and will be heartily supported; while that which only helps by not taking out a shilling is lost to sight. Still, a few enlightened folk do recognise such advantages, and their support gradually brings with it that of their less thoughtful neighbours. Every effort, then, should be made by those interested in this branch of electrical engineering to see that those with whom they are brought into contact fully understand both direct and indirect advantages. Tramway companies may easily be considerable gainers, although the cost per mile run with electricity is equal to that where horse-flesh is used. In the construction of new lines, for example, the cost would be considerably lessened if an overhead system was used, though, unfortunately for electrical engineers, this cannot be done in the majority of cases in England. Even considering the extra weight of car and battery, when a battery has to be used, and the precautions to be taken in the construction to carry the extra weight, the wear and tear is practically confined to the rails, and not to the track, so that cost of maintenance of road is decreased.

PACINOTTI v. GRAMME ARMATURES.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—In his "Notes on Dynamo Construction," Mr. Sidney F. Walker refers to some experiments I made on the above three years ago. In my articles describing the results occur these words: "The function of the projections is to decrease the resistance of the magnetic circuit, and the condition of low resistance is, in this case, realised by bringing a portion of the armature core in close proximity to the poles." Again, occurs the passage: "The only electrical advantage to be gained from the projections takes the form of a diminished resistance of the air space for a given area of the polar surface." The object in view was thus clearly stated, though it depends on the construction of the machine whether the gain due to a diminished air resistance is large or worth securing. As a matter of fact, Messrs. Paterson and Cooper have been making their general run of machines with smooth cores for the past eighteen months, finding it better to increase the copper on the magnets than to tool out the armature projections. There are electrical reasons for making machines giving large currents with Pacinotti armatures into which I need not at the moment enter, but for ordinary types it is only a question of copper *v.* machinery.—Yours, &c.,

London, July 28, 1888. W. B. ESSON.

THE SOLUTION OF THE MUNICIPAL RAPID TRANSIT PROBLEM.*

BY FRANK J. SPRAGUE.

The presentation of this subject before the American Institute of Electrical Engineers for discussion seems to me most opportune. It is a question of great importance, and one for which a definite solution is fast becoming imperative. To those of us who believe that the solution is to be found in the application of electricity, it has a special significance, and I trust that what I say may bear fruit by starting a general discussion of the subject, not only among electrical men, but the general public as well.

More attention is now being paid to the question of tramway traffic than ever before. The reason is not only the comparatively high cost of operation under the present almost universal system of horses, but also because the public are beginning to feel, and the street railway men are beginning to see, that it is a system behind the times. Laying all humanitarian questions aside, the public demand a better and a more rapid service. Railway men want to give it, provided they can do so for the same or less money than they are now spending.

To quote from a New York evening paper:

"The rapid transit question has steadily pressed its way to the front of subjects demanding immediate attention, until it now stands in this city the foremost question of the hour.

"The fact is made evident by the eager discussion upon every hand of the very best means by which the end may be attained with the least possible delay. The total passenger traffic—that is, the total number of persons carried—of this city, has increased at the rate of 140 per cent. in each period of ten years since 1866, and is now something over 325,000,000. At the same rate of increase it would amount in 1890 to over 500,000,000, and in 1900 to 1,225,000,000."

There is every reason to believe that the through traffic will increase as much as expected, because the city is

* Read before the American Institute of Electrical Engineers, June 19th, 1888.

Digitized by Google

growing rapidly and its business section is continually enlarging and pushing northward, forcing the larger part of the population, especially the labouring classes, to seek homes in the upper portion of Manhattan Island and the Annexed district, where rents, already increasing because of the increased facility of access, are still lower than can be readily commanded for business purposes in the lower part of the city. The elevated roads of this city, although carrying 500,000 people a day, do not answer the requirements of rapid transit, either local or through; nor is it possible for any two-track railway to do so.

By rapid transit we do not mean merely through transit; we ought not to consider alone the methods of transportation from one end of the city to the other, or from the city to the suburbs; we are likewise called upon to find some means by which the local traffic shall be benefited. Everything which lessens cost of operation, increases speed, reduces intervals between cars, increases the number of cars, and makes extensions possible, aids rapid transit, no matter whether surface, underground, or overhead.

With the same cost of operation, provided the motive power is materially cheapened, a greater number of cars can be run, intervals can be shortened up, large cars can be run in the place of small ones, better attention can be afforded, cars can be better heated, lighted, and cleaned, they can make better time, people can be carried further for the same money, branches can be opened in districts which would otherwise not pay, and, what is all important, more passengers can be carried, and for this reason alone more money can be made. For years an attempt has been made to replace the horse with motors of various descriptions—compressed air engines, fireless engines, hot-water and soda motors, naphtha and petroleum engines and steam engines. But we can safely say that the question has to-day narrowed itself down as between the cable and the various electric systems for surface work, and between electricity and steam for elevated or underground work.

In order that we may be in a better position to judge of the comparative economy and the relative advantage of present and proposed methods of traction, I will briefly consider, first, the use of horses.

Two distinct methods are recognised among street car men in the handling of their stable equipments. In one, the stock of horses is kept as low as possible; they are worked hard, making fourteen or fifteen miles a day, and the depreciation is very heavy. In the other, the stable equipment is increased; the horses are kept in excellent condition; their average daily duty is reduced to ten or twelve miles, and the depreciation is lessened.

Assuming the cost of a horse as 150dols., and the cost of feeding and caring for him as 180dols. per annum, it would seem that any accurate knowledge of the average life of horses under different days' duty would soon determine the proper amount of the latter.

All railway returns do not, strange as it may seem, give accurate information on which such estimates of cost can be made; but from such facts as are given we may deduce the following: Taking the returns for 1887 for the five largest roads in Massachusetts, we find that they show 6,909 horses and 1,410 cars; that the mileage made was 12,834,665, and the passengers carried 76,187,842.

Dividing the average daily mileage by the number of horses, and multiplying the number of horses in a team, we find only 10·26 miles as the average daily duty for all teams, sick or well. Horses which are on duty make from 12 to 14 miles. On the West End road of Boston, now the largest street railway combination in the world, having about 212 miles of track and over 8,000 horses, 10 per cent. of the horses are counted as being off duty from illness, sprains, shoeing or other causes; and the balance of the horses average about 12 miles a day. A car day is estimated at 10 to 11 hours, and from 45 to 50 miles, and eight horses are allowed as the active force.

The rule given me by one of the officials of this company as a fair one to determine a stable equipment is, to divide the total daily mileage by the miles made in a car day and multiply it by nine, adding what is necessary for hill horses. Hence, if 50 miles is a car day duty, a daily run of 1,600 miles would require a stable equipment of 288 horses, besides those for hill work.

On the Fourth-avenue line in New York, the stable equipment is determined as follows: A car day is 11 hours, and eight horses make about five trips, aggregating about fifty miles. To this number is added 10 per cent. for illness, sprains, &c., and 10 per cent. for emergencies. On this road is illustrated the influence of an important factor in horse car work—that is, the position of the stables. Horses from the upper stable are limited to eleven miles, or otherwise they would have to make twenty-two miles, while horses from the lower stable have to make about 13½ miles, or considerably more.

The average cost of motive power per car day throughout the United States, that is, for from ten to eleven hours, and trips aggregating from forty-five to fifty miles is about 4dols. This counts only those horses on actual duty on the road. The cost of motive power per car day for equal mileage in Richmond is less than 2dols. on the heaviest sort of grade work. The total operating expenses of a horse railway average for the five largest roads in Massachusetts 25.15 cents, and for all the roads in Massachusetts 24.7cents per car mile; and the ratio of operating expenses to gross receipts is, for all the roads, 86 per cent.

The cost per day per horse, based upon the returns of four of the largest roads in New York, is 54 cents, and the cost per car mile from 9½ to 10½ cents.

In addition to the regular depreciation, there is ever present danger of an epidemic in hot weather.

Since the cost of the motive power alone—that is, the cost of harness and stable equipments, horse-shoeing, renewals, provender, hostlers, &c.—is 40 per cent. of the total operating expenses, it will at once be seen how vitally important any material saving in the cost of motive power becomes. If, as we claim, the cost of motive power in an electrical system is one-half or less than that in a horse system, the percentage of gross receipts available for interest and dividends is more than doubled.

Furthermore, when we remember that the average running time for horses is only five to six miles per hour, we have another reason which consitutes an unanswerable objection to the use of horses for rapid transit.

Among the systems which have been proposed to take the place of horses and which has given the most promise, and met with the greatest success where heavy grades and traffic exist, is the cable system. With its general features you are probably familiar.

There are, however, a great many objections to it. One of the most serious is the great initial cost of the construction and plant, the cost of the conduit alone ranging anywhere from 50,000dols. to 80,000dols. per mile of single track, making the investment so large that none but roads having heavy traffic can permit of the expense.

The conduit is necessarily large and costly in order to accommodate sheaves of sufficient size to prevent too great a loss in friction, and on account of the position of the cable and pulleys it is difficult to clean it. This large size also makes it difficult to construct a conduit which will not, because of the traffic and weather strains, be distorted and have the slots forced together or apart. The depth varies from two to three feet, more often the latter, and in any city street this is almost certain to interfere with steam, gas or water pipes.

Each section of the line being a unit and operated from one cable, a break in the cable will suspend the entire traffic of the section.

A broken strand is apt to foul the grip and pile one car on top of another, as happened in Philadelphia, or suddenly start a car which is at rest, as recently happened on the 125th Street line in this city. The cable is a heavy, cumbersome affair, 1¼in. diameter, and weighs about 13,000 pounds to the mile.

It is found that it is best to make these cables in 20,000ft. length.

If a cable is stranded it cannot be used until repaired; if it is stretched 1 per cent. it is considered unsafe. These weaknesses of the cable system render it necessary to have a duplicate cable ready for instant use, and a double line of sheaves.

With a full load not over about 20 or 25 per cent. of the power of the engines is actually used for the propulsion of the cars, the balance being for moving the cable. With

Digitized by Google

any light load the efficiency is even less. But it has been found advisable to have even greater power than this, most of the companies having from two to four times as much engine power as is required at any time, and from one and a half to twice the boiler power. This is necessary, because if any part of the cable engine breaks the whole section of the system is disabled.

FIG. 1.—Curves Illustrating Electric Railway Motor Characteristics.

Every turn in a cable brings a strain upon the grips and reduces the life of the cable, and any increase in the speed at which a cable is driven likewise shortens its life.

Difficulty exists in turning corners, expensive drums, and oftentimes auxiliary cables being required. Constant care and attendance is necessary in lubricating the carrying and curve pulleys, and in taking care of the slots and switches, the estimates for Boston being about 3.20dols. per day per mile of single track, requiring the time of one man per mile. It is impossible to work turnouts, cross-overs or sidings without auxiliary cables, or to operate single tracks.

A line once being put in, any extension is expensive and difficult because of the terminal machinery which is necessary and the definite length of the cable.

The speed is limited; a car cannot travel faster than the cable and thus recover lost time, except on down grades; nor can it travel more slowly save by permitting the cable

Digitized by Google

to slip. The regular speed, then, must be the same in the most crowded sections of the street as in the less populated sections.

The starting is often with a jerk, and the whole motion of a lurching, unequal, unpleasant character, exceedingly disagreeable when first experienced.

Success in the cable railway system considered by itself depends largely upon the condition that a line of reasonable length shall be so located as to warrant frequent car service.

The chief advantages of a cable are the cheapness, as compared with horse-power, of operating a heavily patronised road at a comparatively fixed rate of speed with no regard whatever to grade or gravity; but this cheapness is not inherent to the cable system, but due rather to the fact that steam has such a tremendous advantage over horses. The motive power operating expenses vary from 50 to 70 per cent. of the cost of operating by horses.

Now, what is it electricity by some of its systems promises us for the ordinary street traffic? What are its advantages? First, it will do the work, and in a far more satisfactory manner and at a greatly lessened cost of operation than with horses. Electricity is simply an agent for which we have to pay a certain proportion to carry the power of our steam-engines to take the place of the horse. Since not only on levels, but also on the up and down grades, an electric car can be run much faster than a horse car, and because it can be got under way and stopped much more quickly, the mileage with any given number of cars can be increased, the mean running speed increased, and the same time intervals made, with a less number of cars; or, on the other hand, shorter intervals be made with a given number of cars. The equipment will occupy about 35 per cent. less space, the horse space being saved; and this fact, together with the ability to back when necessary, and to quickly gain headway, enables an electric car in narrow and crowded streets to work a passage through where horse cars would be at a dead standstill. Not only can cars run down grade faster, but also with much more safety, because of the possibility of the instant reversal of the motors in the event of the parting of the break-chain; and when arriving at the top of a grade, the faster a motor runs the better. It has not got to be held in to save it.

The riding of an electrical car is far easier than that of any cable or horse car, starting and stopping more easily, and being in a large measure free from lurching and oscillation. The cars are much cleaner. They can be brilliantly lighted, and they can be heated by electricity. There is no dust, such as rises from the heels of horses. The sanitary conditions are entirely altered, and the health and comfort of the whole population is conserved. Stables with all their unsavoury characteristics and the consequent depreciation of the value of adjacent real estate disappear. No sand is needed on the pavements, and the pavements are not so quickly worn out; often no centre paving is necessary. It becomes feasible to operate branch lines, and also combinations of grades, curves, and ill-conditioned streets, which would be prohibitory to any other system. It is not to be claimed that any one system of electric traction has all these advantages; but in some form or other they will be found.

It has been said that an extended system cannot be operated by electricity, that the lines may break down, that a large number of cars cannot be operated simultaneously, especially when bunched up, that wires burn out, that brushes burn up.

True, these things have happened, and in case of defective workmanship or carelessness they may happen again. Although electricity is a force of unknown nature, and we know it by its effects, it is folly to hold that, whatever faults in machinery may exist or accidents occur, they do not come within a very narrow and limited category; and powerful and mysterious as it is, and answering an impulse with the rapidity of lightning, it is at the same time the most tractable and law-abiding agent with which we have to deal.

There is not a freak of which it is capable which we can not guard against. It has not an attribute of which we cannot make positive use. It has no power of damage which cannot be controlled.

The development of its application, the mistakes which have been made, and the accidents which have occurred are but the milestones and guideposts of the highway to success. Were it not for the occasional failures there could be no advance.

As a matter of fact, there is no apparatus for the transmission of energy that compares in simplicity and efficiency with the dynamo-electric machine and the electric motor. There is no machine in existence, which, when thoroughly and well-built and decently cared for, is less liable to get out of order, and will stand harder usage and greater variations of work with a minimum of attendance and care. A motor has but one moving part, and that has a rotary motion. Its torsional effort under given conditions is a constant, and when properly built and proportioned some types have over a wide range the remarkable and unique quality of having this torsional effort vary as the square of the current used, a feature of marked importance in traction work.

As modern as the motor is, the peculiarities of all its phases are just as well known and capable of just as graphic representation and forecast as are those of the steam-engine. This can best be shown by reference to some curves which illustrate the characteristics of some of the Richmond motors, and have the same significance that an indicator diagram has for an engine.

For convenience, these curves are plotted on both sides of the axis of X, Fig. 1. The ampere-turns on one leg of the field-magnet are plotted as abscissæ. The curve O A gives the characteristic of the machine when run as a series dynamo on a variable external resistance at 856 revolutions. B C represents the equation of counter E.M.F. with an initial E.M.F. of 400 volts. I have allowed an increase in the actual resistance of the machine of 10 per cent. for heating and other causes. The speed of the armature, the miles per hour made by a car with the Richmond gearing, the tractive effort in pounds for one motor, and the h.p. units are, for convenience, all laid off as negative ordinates. Equal units of h.p. and torque are laid off as abscissæ, so as to make the maximum points coincident.

The first report and curve which we have to get is the speed of the motor in terms of its current. We have the law that the speed is directly proportional to the counter E.M.F. developed, and inversely proportional to the strength of the field. In other words, the speed curve, E D C, in terms of the current, is plotted from the curves O A and B C, and the speed for any current is found by multiplying 856 (revolutions) by the ratio of the ordinates corresponding to the current.

The next curve with which we have to deal is that of the work of the motor in terms of the current; that is the curve O F C, which intersects the axis of X and at the same point as the curves of speed in terms of the current and the counter E.M.F.

A third and most important curve is that of the work of the motor in terms of its speed, which is the curve O D G plotted from the curves E D C and O F C, with the horse-power units transferred to the axis of X as abscissæ. For instance, following the regular ordinate for 30 amperes, we find, at the proper intersection, a speed of 630 revolutions of the armature, or 4·82 miles per hour of the car; and, at the intersection of the work curve, that 11·65 h.p. is developed. These two values give us the point S as one of the points of the work curve and so on.

Referring to the work required to be expended on a car, we have from the formula:

$$\text{h.p.} = \frac{w\,n}{375}\left(\frac{k}{2{,}000} + \sin\theta\right),$$

where w = wt. in lbs.;
n = miles per hour;
k = resistance to traction in lbs. per ton on level;
θ = angle of grade.

This gives the work which is required for any grade, speed, and weight. Hence, for any given conditions we can plot the equation, h.p. $= a\,n$, and by its intersection with the curve O D G find at what speed the car will be moved by the motors, and what current is required, if we know the gearing. On the other hand, if we assume that a certain

Digitized by Google

load on a certain grade shall be handled, and we elect that it shall be done with a certain efficiency of the motor, or on a certain part of the work curve, we can draw the car curve for this intersection, and then deduce the speed of the car and, from it, what must be the ratio of gearing to enable the car to be handled by the motors under these conditions. Four of such car curves are drawn—O R, which shows the maximum which could be moved; O M, which shows what can be done at 50 per cent. efficiency; O N and O P, showing the equations which are constantly used in practice. In the actual computation 10 per cent. extra is allowed for losses from friction and so forth.

With the Richmond gearing, and a car equation, h.p. = 4·8 n, we would have a car weighing 14,700lb. sent up a 10 per cent. grade at 4·82 miles per hour, and each motor would take 30 amperes of current. If the grade or weight were increased, the curve O N would be carried towards O M; or, if the ratio of gearing is changed, then, with the curve O N in its fixed position, the weight of car or the grade could be increased, although the speed of the car would be reduced. Other curves are shown; L K showing the tractive effort of the motor in terms of its speed, and O H showing the tractive effort in terms of the current; the tractive effort varying, of course, as the work divided by the speed.

The variety of problems which can be worked out from these curve sheets is very large, and they become of vital importance in dealing with any new work. Nothing could show more clearly the value of a mass of iron in the field-magnets (as I have always held to be the proper method of building motors), and the exceptional qualifications of motors for tractive purposes. Any change in the switch or any change in the potential will vary these curves materially. One fact, however, is to be noted. No matter how the field may be changed, the speed of the motor at 50 per cent. efficiency is a constant.

The connection of the motor to the driving wheels has been attempted in a great variety of ways, and nearly every mechanical device possible has been used. Often the motors are carried upon the car body and connection made with the wheels, which should bear a variable position relative to the car, by means of friction wheels, sprocket wheels, and chains, or by belts, ropes, or wire chains with tightening devices. The motor armature has been mounted directly on the axle, and also hung on a frame between the axles, being connected to both wheels by cranks and side rods, necessitating equal speeds of revolution of the motor armature and the wheels.

These methods are all crude and unsatisfactory. They are makeshifts, and ignore the most important and essential facts which have been developed in car and motor construction. There is, to my mind, only one good way to connect a motor, and this is to centre the motor upon the axle, supporting it flexibly from the car body or the car truck, and driving by gearing with one or two reductions according to the service which is demanded. This is the only way in which an absolutely safe and positive connection can be depended upon both for ordinary work and for the normal and sudden strains called for in an emergency.

Properly made, the friction of this method of reduction is very low, the motion is smooth and free, and reasonably noiseless.

The proposition to couple the motor so that it shall make the same number of revolutions as the axle, ignores one of the most important points which makes light weight in motors possible, and that is the high speed at which the armature can be run.

I have pointed out, in describing the curve characteristics of a motor, one of the essentials to determine the proper ratio of reduction for any motor when required to do a given work. I may here add a brief formula, which will also serve as an index in this matter:—Let f equal the maximum velocity in feet per minute at which an armature at any time is allowed to travel; n, the number of miles per hour to be made by the car; D, the diameter of the car wheel in inches; d, the diameter of the armature in inches. Then the ratio of the gearing must be expressed by the equation—

$$R = \frac{f D}{88 n d}.$$

For instance, let $f = 4{,}000$, $n = 12$, D = 30, and $d = 10$—*i.e.*, about the values which exist in street car work. Then

$$R = \frac{4{,}000 \times 30}{88 \times 12 \times 10} = \frac{125}{11}$$

and this should be made in two reductions. As in our largest trucks, let $f = 4{,}000$, $n = 35$, D = 42 and $d = 18$. Then,

$$R = \frac{4{,}000 \times 42}{8 \times 35 \times 18} = \frac{100}{33}.$$

In the application of electricity we are limited to no one system; we have a choice which will permit us to meet any exigencies or conditions of traffic. There are two kinds of application.

In one each car is perfectly independent of the other, receiving its charge at the central station and acting as an individual unit. The storage battery method is such a system.

The other is a system of direct supply, and unlike the battery system, where the energy of the steam is four times converted, it suffers only two losses. In this system the current is delivered directly to the line, from which the motors as they move along derive their current. There are several forms of conductors, centre, and side rails, the main tracks, conductors carried in conduits, and overhead. Either a complete metallic circuit may be used, or one conductor with the rail and earth return. The machines can be operated under three different systems—the series, multiple series, and parallel circuit distribution.

Of these various plans, I shall discuss only three—the storage battery, the conduit and the single overhead wire system with underneath contact carried on the car, and for the systems of distribution the parallel circuit system only.

The storage battery, from the time of its first introduction to the public, has offered a tempting solution to the application of electricity for surface transit. The great advantage of the battery system is that, while most of the advantages of an electric system are retained—such as perfect control of the car, ease of manipulation, cleanliness and so forth—each car in itself becomes an independent unit not dependent upon any general accident to a system. As attractive a solution as the storage battery at first sight seems, there are many points of disadvantage in the present state of its development. One of the most important is the excessive weight of battery which is necessary under the conditions of service which are met with in this country, from 3,400lb. to 4,000lb. being the ordinary weight. Not over 10 per cent. of the lead in these batteries is actually used for storage. On account of the weight and the room which the battery takes up, there has to be a radical change in the construction of the cars; and while old cars can be made use of by a great deal of patching, it is not advisable to attempt this. This change makes the present cars useless, and likewise increases the cost of new car bodies.

Then again, while the tracks as they exist may stand the additional weight of motors on a four-wheel car, the additional weight of battery, making the total weight on a given wheel-base double what it was before, will render it necessary on a great many tracks to relay the road-bed or to put in 8-wheel cars. Of course these objections are not so serious on a new road as they are on an old one.

But I confidently expect to see, in the not so very distant future, the weight of battery necessary to handle a car reduced one-half; this, besides overcoming some of the objections which exist now, will halve the expense of handling them at the central station, and will also allow the present standard width of aisle to be maintained.

The present excessive cost and unknown depreciation of the battery, its lack of efficiency, limited capacity, the fact that only a portion of the charge can be taken out with safety, and the reduction of its output when sudden demands are made upon it, are all of such a character as to leave wide room for improvement. The loss of efficiency in conversion I do not esteem of such vast importance, because in any large system where the engines are kept going under a steady load, the cost of operation will not be so very much more than where operating under continually varying loads. The limited rate of discharge, as well as the limited

Digitized by Google

capacity, limits the grade work to which a battery car can be subjected. For instance, as batteries and cars are now made, we can easily have the following combinations of weight:—

	Pounds.
Weight of car	5,000
Batteries	3,600
Motors and other apparatus	2,000
Sixty-five passengers	9,100
Total	19,700

To start and to accelerate this load on, say, a 6 per cent. grade, demands a discharge rate which no storage battery company cares to recommend.

As near as it is possible for us to get at a correct estimate on a new road of moderate grades, a storage battery system could be operated at about 80 per cent. of the cost of operation by horses. This is about double the cost of the direct system of supply on a large scale.

But the storage battery is not going to stand still.

Many men with abundant capital are striving for improvement, and I think there is but little question that batteries will be reduced in weight, increased in capacity, and made far more efficient and long-lived.

The conduit and overhead systems have one point in common. Both are dependent upon a central station, and the actual cost of operation (except for the care and maintenance of the conduit itself) would be about the same. There is, however, a great difference of investment. Both must have about the same amount of copper, and, to be effective, about the same distribution.

The difference of cost, then, is practically the difference between pole erection and conduit laying, and this will be from 25,000dols. to 30,000dols. per mile. As an investment, of course, it means that with the conduit very much more money has to be earned. The electrical conduit can be built for less money than a cable conduit, because it can be made of less depth, but it cannot be built without due regard to the strains of street traffic and weather, and with proper drainage and cleaning facilities. The advantages of the conduit are chiefly that there are no overhead obstructions. Its disadvantages are, besides its great cost, the lack of cleanliness, increased possibilities of leakage, and greater difficulty of repair in case of accident. Recognising, however, the demand which exists in certain places for a conduit, we have developed such a system which has many of the same elements of simplicity and reliability that our overhead system possesses.

The working conductor carried in the conduit is divided into sections, which at intervals of every block or half block, as desired, are connected through automatic cut-outs in manholes to the main conductor, which is continuous and enclosed in a lead or iron covered cable. Any accident to a section, such as flooding, short-circuiting, and so forth, will simply cut out that particular block.

For the immediate solution of the question of more rapid and cheaper transit in many places the overhead system is most available.

I am aware that a great hue and cry has been raised, especially of late, against any electric wires whatsoever being used above ground. The feeling which exists is not entirely unreasonable; in fact, it is easily accounted for by the most casual inspection of the condition of the wires of this city. But many of the objections which are raised against all overhead systems are not necessarily inherent; they are very largely due to gross carelessness in construction engendered by a faulty municipal administration. We have in our cities little or no active control or oversight of the wires which have been put up in our streets. Year after year, from the earliest telegraph days, those in control have granted to telegraph, electric light, telephone and electric power companies innumerable more or less limited franchises for stringing or hanging wires through our streets. These permits have often been granted without any restriction whatever; they are often granted for a "consideration." The erection and maintenance of these lines being a large factor in the cost of construction and operation of the companies, they have been put up with little or no regard to public convenience or safety—certainly with no regard to any æsthetic tastes—and oftentimes with an utter ignorance of the proper methods of construction. Fire-underwriters, in their wisdom, have demanded an insulation to stand fire, forgetting, or in apparent ignorance of, the fact that protection from moisture and leakage is of far more vital importance. Hence we have that treacherous wire known as "underwriters' wire," or more commonly among electricians, "undertakers' wire."

The poles have, until lately, been of the cheapest construction, badly set and continually marred and weakened by the spurs of the linemen. New lines have been continually added, and poles intended originally for a certain number of wires are now carrying double or treble that number.

The electric light companies, after cutting out a lamp for which a contract has expired, leave the bights of their wires hanging in loops. The telegraph and telephone companies allow thousands of miles of "dead" wires to remain overhead, or to hang in festoons from every pole, which in some sections are utilised as clothes-lines or are used by the street urchins as kite traps.

They cross and recross the street at every angle, every elevation, and at every tension. They are strung surreptitiously on poles to which no right exists and over buildings for which no permit has been granted.

No one seems to have the power to compel a change or improvement in these practices, and the companies themselves never will do it until so compelled. The sharp competition in the lighting business, the small profits derived therefrom, the great trouble of hauling down and getting rid of miles of dead telephone and telegraph wires, all these interfere with a satisfactory straightening out of the existing system of overhead wires.

In all improvements for public convenience we have to consider the arguments for as well as against such improvements. It is not sufficient that we say that there are disadvantages attending the introduction of the system, but we must consider likewise the possible advantages; and this is especially important when we consider the use of the overhead line in a system for propelling street cars. Such a line being part of an investment of a company which has practically no competition on its own streets, and whose own interest would require it to keep its line in first-class condition, can be put up in a manner presenting few of the objections which are generally urged against a system of overhead wires. I would not urge its adoption for all places, but in all suburban districts; for comparatively narrow streets, for all streets operating under an elevated railway structure, or where the tracks are near a side walk, the direct system of supply from an overhead line with underneath contact, presents advantages which, once appreciated, far outweigh the possible objection of such a system.

Several methods exist in which the wires can be erected. One in which span wires, at a distance of 125ft. apart, reach across the street from building to building, or from pole to pole, and has suspended from it, directly over the track, at a height of about 19ft., a longitudinal wire of not more than a quarter of an inch diameter, this wire being termed the "working conductor." This should be of the very strongest character. It should have a high elastic limit, great tenacity, and resist corrosion and oxidisation.

Its conductivity is a matter of less importance, since not upon it, but upon the main conductor which supplies it, do we depend for the main transmission of our current. Hence the elements of strength and reliability are of far more importance than conductivity. We have found that the best wire for this purpose is that alloy known as "silicon bronze"—a wire which can be drawn for a tensile strength of from 75,000lb. to 150,000lb.: that is, a strength higher than that of the best commercial steel. Such a wire it is almost impossible, under conditions of service, to break, and its life is very long. Samples of hard-drawn copper wire, which possesses only from one-third to one-fifth the tensile strength of this wire, show, after months of the severest usage, scarcely any signs whatsoever of abrasion or reduction in size. This wire is of the same size, whatever the distance run or the number of cars operated, and the main conductor may be stretched along the buildings, through a side alley, along poles, underneath the elevated structure, or buried underground.

In the latter case there would be in a single-track street only one longitudinal wire, and that one over the track,

Digitized by Google

and it would be no larger than a single telegraph wire; and in the case of a double track there would be only two wires stretched longitudinally along the street, and these would be as taut as harp strings.

Switches and cut-outs are put in main and working conductors in such a way that the different sections can be operated independently, and cut out automatically or at will. The span wires can be as much above 19ft. from the ground as is desired. Of course, where a telephone or electric light line crosses the street, and may break and fall upon such a conductor, it would be necessary to have one or two guard wires above it.

These guard wires can be very properly carried from the span wires themselves. Furthermore, if desired, the stretches between the span wires where the guard wires are used can be very much longer than 125ft. They can be even as long as 500 or 600ft.—that is, two or three city blocks—in which case the two guard wires form a light suspending structure, from which, at intervals of 100ft., the middle wire is carried in a straight line.

In very many cases, it is unnecessary to have any span wires whatsoever. In those streets where the track runs near the kerb, a light pole with an ornamental bracket is all that is necessary.

In a broad street, where the tracks occupy only a small portion of the street, and are near together, a line of poles of ornate design, with light arms projecting on either side, can follow the centre of the street. Oftentimes, there is a middle division or park, such as exists on the Boulevard in this city, which will afford space for the poles without interfering with anything. These same poles can be used for lighting the street. On streets occupied by elevated railroad structures, the structure itself can be used as a support for the overhead wires.

Among the numerous places in New York where an overhead system could be put in perfect operation are Eighth-avenue, from Fifty ninth-street up; the Boulevard, from Fifty-ninth-street up; a part of the First and Second avenue lines; the Third, Sixth, and Ninth avenue lines, and all the suburban extensions in the annexed district.

To avoid any extra strain on this wire, the current is taken off by a flexibly-supported trolley carried on the car, and making contact underneath by upward pressure, as will be more specifically described later.

With such a system put up in the proper manner, it is almost impossible for any accident to occur which will disable the line or prove a hindrance or annoyance to the public in any way.

The wires are perfectly clear of the operations of the firemen, and should they in any place interfere the obstructing section can easily be cut out without disabling the remainder of the system.

The question of "E.M.F.," or electrical pressure, so to speak, to be used, is one of great importance. I do not favour going above 400 volts, and this on a continuous current circuit. This is less than one-seventh the E.M.F. which exists on many of the arc light circuits in this city; and the current being of a perfectly smooth and continuous character is free from the danger which might be feared from a current of equal E.M.F. of the alternating or pulsating character. In point of fact, in Richmond, a very large number of our men have received the full E.M.F. from our line without any injury.

On a dry day, the trolley wire has lain coiled up on the ground while the cars are in operation; and while certain changes were being made in the overhead circuit, the men work continually with the current on the line. I have never known a constant potential current of 400 volts to cause of itself the death of or serious injury to a human being.

The past year to me has been one of great responsibility and wide exerience. It has been a hard year. But the experience and expense are as nothing compared with the great value of having been with my associates instrumental in bringing to a successful issue one of the most important pieces of electrical engineering with which I have ever had anything to do. Among the roads which we have equipped the most important is, of course, the Richmond Union Passenger Railway, which now has six times as many machines in operation as any other road of its character in existence, at which every difficulty to be encountered in an overhead system on heavy grades and with sharp curves has been met, and which has for all time conclusively settled the question of the economical operation of a large road by the method of direct supply.

I will briefly refer to the road, giving some illustrations of its principal features, and some facts about its operation.

Some idea of the character of the road may be gathered from the following: The total trackage is about twelve miles. It runs a very irregular course and reaches the principal parts of the city. About nine miles of street are covered. The central section is a double track for a distance of something over two miles, a part being laid on paved streets, and the balance on macadam or unpaved streets; all the extension and branch lines are on unpaved streets, many of them in clay soil, which, in wet weather, covers the tracks, and where it would be an impossibility to operate horses without paving. The double-track section partly encircles the old State Capitol, and presents difficulties rarely equalled elsewhere. This part of the line, in a distance of less than 1,000ft., has, on both east and west-bound tracks, four curves, the inner rails of the west-bound track being of about 27, 30, 40, and 50ft. radius. The power necessary to run these sharp curves is much increased by the fact that grades are encountered on the curves as high as 8 per cent., and the lay of the street has required some of the outer rails to be some inches below the inner ones. Running eastward from the Capitol, the road descends to a low valley through a series of grades, varying from 3 to 10 per cent., and then ascends a series of sharp grades and curves in a new district to one of the car houses.

Going west from the State House, the road rises to nearly the highest point in the city, and then runs through a residential district across the Richmond, Fredericksburg, and Potomac Railroad, and, after several sharp curves, extends back a further distance of two miles to a second car-house beyond the new reservoir. Two branches connect with its main line, one leaving at the old Market Place crossing, and paralleling the Chesapeake and Ohio Railroad, and terminating at its machine shops. The other runs into what is popularly known as "Africa," a section almost exclusively inhabited by coloured population.

(To be continued.)

COMPANIES' MEETINGS.

ANGLO-AMERICAN TELEGRAPH COMPANY.

The half-yearly general meeting of the Anglo-American Telegraph Company, Limited, was held on Friday last at Winchester House, Old Broad-street, the Marquis of Tweeddale, presiding, in the absence, through indisposition, of Viscount Monck.

In moving the adoption of the report, the **Chairman** expressed satisfaction at the decrease of £1,100 in the working expenses. The repairs of cables had cost £5,981, as against £9,858 in the corresponding period of the previous year. That was accounted for by the fact that the expenses of the "Minia" had been charged to renewal fund, for the reason that the ship had been employed in renewing a very considerable portion of cable that had been destroyed. That had cost £15,485. The repair was in connection with the Brest-St. Pierre cable, which had been found broken in three different places, one break being at a depth of no less than 2,000 fathoms, the second at 400 fathoms (and both of those breaks had been repaired), and the third at 900 fathoms. They had every reason to believe that news would reach them in a few days of the successful repair of that break also. These repairs had been costly, but fortunately they a fund to draw upon to pay for them. The renewal fund now amounted to the handsome sum of £909,694, but the securities in which that fund was invested would yield now about £50,000 in excess of their cost price. He regretted that there had been a reduction of £19,635 in their receipts, owing to the Commercial Company lowering their rate from 1s. to 6d., the same tariff as the Company was charging. The 6d. rate had been adopted in the hope and belief that it would prove a remunerative tariff, but the experiment had now extended over two years, and in common with all the Atlantic telegraph companies they had come to the conclusion that the 6d. tariff was not only not remunerative, but that it would not become so within any reasonable time. For the first year the results obtained with that tariff were very satisfactory, the increase in the traffic amounting to about 140 per cent., and if that increase had gone on they probably would not have had to alter the rate. The increase, however, ceased about a year ago, and therefore they knew pretty well the effect of the 6d. tariff upon their finances. Negotiations were now pending for raising the rate to 1s., and there was a reasonable prospect of their being concluded in a satisfactory manner, and within a very

Digitized by Google

short time. If, as they believed, the adoption of a shilling tariff would not lead to any serious reduction in the number of messages, the revenue would benefit very considerably, and he need hardly add that they hoped for a better dividend than it had been their duty to propose on that occasion. Their lawsuit with the French company had been gained by the Company, and large damages had accrued to them in consequence. No credit, however, had been taken in the accounts for any portion of those damages. He might add that claims had been made by the French company, which had somewhat delayed the negotiations to which he had referred.

Sir James Anderson seconded the motion.

The **Chairman,** in reply to questions, said that many people of great knowledge on the subject had fully believed that within a reasonable time the 6d. tariff would pay, on the same principle that lower rates had led to large increases of business in railway, omnibus, and other companies, not to speak of the great success which had attended the Post Office reductions of rates. One advantage of the low tariff had been that they had kept off competition. If they raised the rate beyond 1s., he was not sure that some competing schemes might not crop up in the future. The Directors had no intention of writing down the capital.

The motion was carried unanimously.

A discussion followed on a motion proposed by **Mr. T. Smith,** and seconded by **Mr. John Newton,** expressing the opinion of the meeting that it was desirable that from the 1st inst. the whole of the interest arising from the investments of the renewal fund should be carried to revenue account.

Mr. Gueedon protested against any interference with the renewal fund, and moved an amendment to the effect that the disposal of the interest on the investments forming the fund should be left to the discretion of the Directors.

Eventually, on a show of hands being taken, the **Chairman** declared the amendment carried.

SUBMARINE TELEGRAPH COMPANY.

The half-yearly ordinary general meeting of the proprietors of this Company took place at the Company's offices, Throgmorton avenue, London-wall, on Tuesday. Sir Julian Goldsmid, Bart., presided, and there was a large attendance of shareholders.

The Directors' report for the half-year, ending 30th June last, stated that the joint earnings of the two companies amounted to £67,397, and the working expenses to £27,788. The joint earnings were £2,663 more, and the working expenses £521 less than the corresponding period of 1887. The result of the business for the half year enabled the Directors to add, as usual, 15 per cent. of this Company's proportion of the receipts to the reserve fund, to recommend a dividend at the rate of 13½ per cent. per annum, and to carry a balance of £261 to next account. The number of messages transmitted in the six months was 1,717,311, containing 19,073,919 words, against 1,618,634 messages in 1887, containing 17,901,009 words. All the Company's cables, as well as those worked by the Company, were in good working order. The Company's steamer, "Lady Carmichael," had been thoroughly overhauled in the course of the half-year, at a cost of £907, of which £500 had been charged in the annexed accounts, and the balance would be charged against the revenue of the next half-year. The steamer was now in excellent condition, both as to her hull and general machinery, and had been surveyed by Lloyd's surveyors, who had classified her as a vessel of the first class. The negotiations between her Majesty's Government and the Board, referred to in the last report, had been continued during the half year, and were now on the point of completion. As soon as an agreement had been finally arrived at the Directors would forthwith lay it before the proprietors for their approval.

The **Chairman,** in proposing the adoption of the report, together with the statement of accounts, said the observations he had to make that day were very short indeed, and very simple. They would see that there had been a fair increase in the traffic during the six months which was under review. The number of messages and words transmitted over the Company's service were given in the report, but the average length of the messages was not, and he dare say that it was of interest to many people. The average length of messages during the last half-year was 11·06 words, and during the half-year then under review it was 11·11, showing a very slight improvement in the length of the messages. In former years he had told them, when there was a complaint of the diminution of the number of words in the messages, that he thought they must come to a termination of that reduction before long, and when he had been asked to fix the figure at which it would terminate he had said that he could not imagine that it would go below 11·0. It had, however, gone slightly below 11·0 on one or two occasions, but he thought that was the average. With regard to the concession, they all knew that it would terminate very shortly. He had mentioned on previous occasions that not so very long ago they had great hopes that the concession given them by the French Government would be renewed, and had it not been that a very strong opinion had been entertained by the English Government he believed that would have been the case, but, like sensible men, a decision having been come to, the Directors had thought it was in the interests of the shareholders of the Company to make the best of it. Ever since, therefore, they had been in active communication with the English and French Governments upon the subject of taking over the property of the Company at the termination of the concession. On the last occasion Mr. H. Brand, who then presided, told them that the negotiations were progressing, and although they had come to an arrangement with regard to several points raised, there were still some which depended partly on the English Government, and partly on the French Government, which had still to be settled. Consequently, he was not in a position to day to state the absolute result of their negotiations. The shareholders had always reposed the greatest confidence in the Board, and he assured them that he and his co-directors were doing their very best in the interests of the Company. It would be gratifying to them to know that they had maintained their cables and ships, and, in fact, all the property connected with their business, in the very best possible condition, and he believed there was no telegraph company in the world that had a better plant or machinery than they had. He concluded by formally moving the adoption of the report.

The **Hon. Ashley Ponsonby** seconded the motion.

In the course of a brief discussion which followed, **Mr. Soden** urged the importance of shareholders in other submarine telegraph companies to protect their interests in case the Government should step in and claim their right to the foreshore.

The **Chairman,** in reply, assured the hon. proprietor that the interests of the shareholders would be protected. It was not only the English Government with whom they had to deal, but the French and also one or two others. If they had not attained the success they desired it was not owing to any fault or neglect of the Board, but due to circumstances over which they had no control.

The motion for the adoption of the report was then unanimously agreed to.

The retiring Directors, the Hon. Ashley Ponsonby and the Hon. H. Brand, and the Auditors having been duly elected, a cordial vote of thanks was passed to the Chairman and Directors, and the meeting terminated.

GLOBE TELEGRAPH AND TRUST COMPANY.

The 15th ordinary general meeting of the Globe Telegraph and Trust Company, Limited, was held on Friday at Winchester House, Old Broad-street, Sir J. Pender presiding.

In moving the adoption of the report, the **Chairman** observed that on the present occasion their prospects were brighter than when he last addressed them. The Eastern and Eastern Extension Telegraph Companies had in a great measure recovered what they had been obliged to sacrifice at the Berlin Telegraph Conference, and there was now a prospect of seeing increased rates charged by the Atlantic cable companies. He might also state that the prospects of their other investments were all encouraging. They now proposed a dividend on the ordinary shares which would make the total distribution on those shares for the past year £3. 10s. per cent., against £2. 7s. 6d. per cent. for the previous year; and he found that from the beginning they had always paid their preference dividend of 6 per cent., while the average dividend on the ordinary shares had been 4·48 per cent. On the combined shares, the average dividend paid by the Company from the beginning had been £5. 2s. 4d. per cent. On about the 1st of September, he believed that the rate charged by the Atlantic cable companies would be raised to 1s., and if with that rate the present traffic of those companies was maintained, the Globe Company would be very beneficially affected. He expected they would be paid off, about the end of this year, for their holdings in the capital of the German Union Telegraph and Trust Company, and in the German Union Telegraph Company of Berlin, whose lines had been acquired by the Imperial German Government. He hoped they would not obtain, in the future, a smaller rate of interest on that particular portion of their capital.

The **Marquis of Tweeddale** seconded the motion.

In the course of a short discussion complaint was made by **Mr. Weatherby** of the expenses.

The **Chairman** said that the capital of the Company was over £3,000,000, and the percentage of expenses for the conduct of such a company was considerably below the average of similar companies in London. Mr. Newton was wrong in supposing that the difficulty of carrying out the proposal for which the Company was originally formed had been caused by the jealousy among the directors of the telegraph companies. As a matter of fact, it was the absence of jealousy among them which had made the submarine telegraph system what it was.

The motion was then adopted, and the retiring Directors and Auditors were re-elected.

SOUTH-EASTERN (BRUSH) ELECTRIC LIGHT AND POWER COMPANY.

An extraordinary general meeting of the South-Eastern (Brush) Electric Light and Power Company, Limited, was held on the 30th ult. at the Guildhall Tavern, Gresham-street, Mr. W. H. Pannell, F.C.A., the liquidator, in the chair, to consider resolutions—(1) for adopting the accounts and report presented by the liquidator (audited and approved by four of the principal shareholders) as to the manner in which the winding-up had been conducted and the property of the Company disposed of, and authorising the liquidator to distribute the balance of cash in hand as proposed in the accounts; (2) authorising the liquidator to destroy all books and papers of the Company and of, or relating to, the liquidation at the expiration of three months; and (3) "That the liquidator do forthwith, in accordance with section 143 of the Companies Act, 1862, report to the Registrar of Joint Stock Companies that the affairs of this Company are fully wound up, and that the final meeting has been held." When the Company went into liquidation there was 6s. 6d. a share uncalled, and the liquidation had been closed with a call of 2s. 3d. a share. It was proposed to distribute 8s. 7d. a share on the 400 fully-paid shares, and ½d. a share on the 17,654 ordinary shares. The total loss of the Company had been £45,953.

The **Liquidator** formally proposed the resolutions *seriatim*.

Mr. Booker moved an amendment to the effect that the books should not be destroyed for a year, in order that the shareholders might have further opportunity afforded them for prosecuting the promoters, directors, and others.

The amendment was not seconded, and the resolutions were agreed to.

Digitized by Google

PROVINCIAL BRUSH ELECTRIC LIGHT AND POWER COMPANY.

An extraordinary general meeting of the Provincial Brush Electric Light and Power Company, Limited, was held afterwards, **Mr. Pannell** in the chair, to consider precisely similar resolutions. On the Company going into liquidation there was an uncalled liability of 5s. a share, and the liquidator had managed to close affairs with a call of 2s. 6d. a share. The balance available for distribution by way of dividend, as return of capital, to the shareholders at the rate of 3 1-3d per share, was £248. 19s. 9d. The total loss of capital had been £51,096.

The resolution having been proposed, **Mr. C. H. Stewart** expressed his sympathy with the observations which Mr. Booker had made at the previous meeting, but said he felt that the liquidator had done the best he could for the shareholders. He considered that the inception and management of the two companies had been a stain on the commercial morality of the City. With regard to the Consolidated Company, neither the South-Eastern nor the Provincial Company had had anything to do with it except that both of them had been drawn upon for its benefit.

The resolutions were passed.

NEW COMPANIES REGISTERED.

Crompton and Company, Limited.—Registered by Ashurst, Morris, Crisp and Co., 6, Old Jewry, E.C., with a capital of £140,000, in £5 shares. Object: to adopt and carry into effect an agreement dated July 16, 1888, and made between R. E. Crompton and Co. of the one part and Francis R. Reeves, on behalf of the company, of the other, for the acquisition by the Company of the business, goodwill, machinery, privileges and other property of Messrs. R. E. Crompton and Co.; to acquire any additional letters patent relating to inventions for the production or supply of heat, light or power by means of electricity, magnetism, or any other agent, or any inventions of a like character, and to take and work any license or business in connection with such inventions. The first subscribers are :—

	Shares.
The Right Hon. Viscount Torrington, Maidstone	1
C. Grant, K.C.S.I., 5, Hyde-park-place, W.	1
F. T. Metcalfe, 4, St. Mary-axe, E.C.	1
J. F. Albright, Savernake Lodge, Chelmsford	1
R. S. B. Crompton, 23, Porchester-gardens, W.	1
H. S. Price, 52, Queen Victoria-street, E.C.	1
E. T. Botwright, 23, Sutton-place, Hackney, E.	1

There shall not be less nor more than seven directors, and the first shall be appointed by the subscribers to the memorandum of association. The qualification of a director shall be the holding of at least £500 in the capital of the company. The remuneration of the directors is fixed at £1,000 per annum.

Metropolitan Electric Supply Company.—The Metropolitan Electric Supply Company, Limited, has been registered with a capital of £500,000, in 50,000 shares of £10 each, being 49,900 ordinary shares, and 100 fully-paid founders' shares, to be increased from time to time as the works extend. The Directors are :—

Sir John Pender, K.C.M.G., Chairman of the Eastern and Eastern Extension Telegraph Companies, Chairman.
Sir George Elliot, Bart., M.P., Director of the Telegraph Construction and Maintenance Company, Limited.
Sir Robert N. Fowler, Bart., M.P., Alderman (Messrs. Dimsdale, Fowler, Barnard and Co.)
Admiral Sir George H. Richards, K.C.B., F.R.S., Managing Director of the Telegraph Construction and Maintenance Company, Limited.
Sir James Anderson, Managing Director of the Eastern and the Eastern and South African Telegraph Companies, &c.
J. Spencer Balfour, Esq., Deputy-Chairman of the Debenture Corporation, Limited.
J. E. H. Gordon, Esq., Electrical Engineer.
J. C. Parkinson, Esq., Managing Director of the Alexandra (Newport and South Wales) Docks and Railway Company.
J. Denison Pender, Esq., Director of the Eastern Extension Telegraph Company, Limited.
John B. Verity, Esq. (Messrs. B. Verity and Sons, Electrical Engineers).
Henry Weaver, Esq., Managing Director of the Anglo-American Telegraph Company, Limited.
H. Granville Wright, Esq., Director of the Hotel Victoria, Limited.

Chelsea Electricity Supply Company.—The Chelsea Electricity Supply Company, Limited, with a capital of £100,500, divided into 20,000 shares of £5 each, and 500 founders' shares of £1 each, has been formed to establish a central station for the supply of electricity for lighting and other purposes in what is described as one of the most important residential districts of London. The Company was founded in November, 1884, in anticipation of alterations in the Electric Lighting Act of 1882, and £1,650 has been expended in securing the necessary parliamentary powers, the agreement for the lease of a suitable site for the central station, in canvassing the district, &c. The system of distribution which will be adopted by the company is one in the economy and efficiency of which the directors have, they state, the fullest confidence. The electricity generated at the central station will be generated by underground mains to sub-centres, where accumulators will be charged. From these storage stations the current will be distributed to the surrounding buildings. According to the prospectus, the Company has obtained information as to the demand for electric lighting in the area to be lighted, and 6,000 lights may be said to represent the immediate demand, with a good prospect that this will be increased within the same area. The present issue is 6,400 ordinary shares, of which 6,240 are now offered for subscription. The Directors are:—

The Rt. Hon. Lord Thurlow, F.R.S., Chairman of the Anglo-American Brush Electric Light Corporation, Limited.
J. Irving Courtenay, Esq., Managing Director of the Electrical Power Storage Company, Limited.
Nugent Daniell, Esq., 17, Lennox-gardens, S.W.
Sir George R. Prescott, Bart., Chairman of Callender's Bitumen Telegraph and Waterproof Company, Limited.
Major-General Webber, C.B. (R.E. retired), Past-President Society of Telegraph Engineers and Electricians.

Committee of Consultation.

T. O. Callender, Esq., Manager of Callender's Bitumen Telegraph and Waterproof Company, Limited.
Frank King, Esq., Superintending Engineer of the Electrical Power Storage Company, Limited.
J. S. Raworth, Esq., Superintending Engineer of the Anglo American Brush Electric Light Corporation, Limited.

"Woodite" Company, Limited.—Registered by Watson, Sons and Room, 12, Bouverie-street, E.C., with a capital of £50,000, in shares of £10 each. Object: to acquire from Mrs. Annie Matilda Wood all or any of certain patents granted in the years 1885, 1886, 1887 and 1888; also the two trade marks "Woodite" and "Whaleite," or any modification thereof, the registered design, models, drawings, stock, trade secrets and other things belonging to Mrs. A. M. Wood and connected with "Woodite," "Whaleite," or any of them; to acquire licenses and vend the same throughout the world. The first subscribers are :—

	Shares.
E. S. Inman, 13, Glazbury-road, West Kensington	1
J. Brunton, C.E., Westminster, S.W.	1
W. Wood, 13, Delahay-street, S.W.	1
S. Long, C.E., 13, Delahay-street, S.W.	1
W. Brown, 19, Campden-hill-road, Kensington	1
A. M. Wood, 13, Delahay-street, Westminster	1
T. H. Bartlett, Garratt-park, Wimbledon	1

The number of directors shall not be less than three nor more than nine, and the first shall be E. S. Inman, J. Brunton, Captain J. W. Clarke and W. Brown. Mrs. Annie Matilda Wood shall be appointed a director immediately after the first allotment of shares. The directors shall be paid £750 per annum, and £100 additional for every 1 per cent. of dividend over 10 per cent., but their remuneration shall not exceed £2,000 per annum.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The traffic receipts of the Brazilian Submarine Telegraph Company, Limited, for the week ending July 27 amounted to £4,592.

National Telephone Company.—The report of the Directors of the National Telephone Company, Limited, for the year ended June 30 states that the gross revenue for the past year is £99,119, against £85,073 for the previous year, and the amount carried forward to next year is £58,495, against £49,525 carried forward last year. The annual rentals on June 30 reached £106,572, against £90,537 at the corresponding date of the previous year, showing an increase of £16,035. There is also a revenue derived from fee messages at the rate of £3,000 a year, against £1,800 last year, making the total gross revenue reached on June 30 £109,572, and giving an increase of £17,235 over the total of last year. After providing for the accrued interest on the debentures, the dividend of 6 per cent. on the first preference shares, the dividend of 6 per cent. on the amount of second preference capital paid up, and after having paid an interim dividend for the first half of the year at the rate of 4 per cent. per annum on the ordinary capital, there remains a balance of profit amounting to £17,003. Out of this the Directors propose to allot a further sum of £11,250 to the payment of a dividend upon the ordinary capital for the second half of the year, at the rate of 5 per cent. per annum, and besides placing £2,500 to the reserve fund to carry forward £3,253. Out of the amount carried forward a sum will be required towards the adjustment of long-standing claims between the United Telephone Company and this Company, now in process of being satisfactorily settled by mutual concession.

PROVISIONAL PATENTS, 1888.

JULY 20.

10,492. **Improvements in holders for incandescent electric lamps.** Charles Scott Snell, Culver Park, Saltash.

10,505. **Improvements in instantaneous make and break electric switches.** Emile Rousseau, 3, Knott's-green, Leyton, Essex.

10,524. **Improvements in electric railways.** Benjamin Joseph Barnard Mills, 23, Southampton-buildings, Middlesex. (The Bentley-Knight Electric Railway Co., United States.)

JULY 21.

10,568. **Improvements in the manufacture of electric bells.** Frederick Henry Boyce, Blake-street, Hulme, Manchester.

10,572. **Controlling train lighting dynamos.** John Harold Woodward, Bernard Mervyn Drake, and John Marshall Gorham, 2, Princes Mansions, Westminster, London, S.W.

NOTES.

Chicago.—The central portion of Chicago is to be lighted by arc lights, run by the city's own plant. It will take 500 h.p., and will be ready in a month.

Personal.—Mr. J. Wright, late secretary of the Maxim-Weston Company, has, we understand, taken the position of manager to the Schanschieff Battery Syndicate.

Bilbao.—The Spanish Government is going to spend a million sterling in improving the port of Bilbao. Some electric lighting plant ought to be wanted for this.

Telephone Calls.—Kansas City exchange is said to have the largest amount of business of any telephone exchange. Its average of calls is 12 for each subscriber per day.

Electric Tramways in Australia.—It is stated that the tramway company of Brisbane is making arrangements to substitute electric motors for the present horse-power cars.

Tenders Wanted.—We understand that tenders are invited for the wiring and fitting up of Messrs. Hampton and Sons' premises, in Pall-Mall East, Whitcomb-street, and Monmouth-court.

Scotch Incandescent Lamps.—The manufacture of a new incandescent lamp of large candle-power has been commenced at Woodside Electric Works, Glasgow by Mr. Rankin Kennedy.

Motor Patents in America.—After ten years' litigation, priority has been given to Mr. Stephen D. Field for the modern type of dynamo electric motor. This decision may have very important consequences in the States.

Brick-making by Electricity.—A 20 h.p. and a 30 h.p. Sprague motor have just been sent to Nebraska to be used in operating machinery for making brick. This is the first application of this nature so far made with such large motors.

"Wild" Electricity.—A new definition of high tension electricity comes to us from Canada, where the telephone electricians talk of the currents used on arc light circuits as "wild" electricity; and that used for incandescent circuits, of course, is "tame" electricity.

Cox-Walker Swinton Magneto Bells.—With reference to the description of this apparatus in last week's issue, we are informed that the Equitable Telephone Association, Limited, of 75, Queen Victoria-street, E.C., have been appointed sole agents for the sale of these instruments.

Alternate Currents.—Banker Moritz Mayer, of Vienna, has his town house lighted with electric light, for which purpose he has a set of 30 accumulators. In the summer he takes these out and fits them into an electric launch, by means of which he careers about the beautiful waters of the Wörthersee. Not a bad idea.

Pacinotti Armatures.—Mr. Esson informs us that the advantage derived from Pacinotti *v.* Gramme armatures is resolved into a question of *copper v. machining*, not copper *v.* machinery, as printed in our issue of last week. In the same letter he mentions that the method of securing the armature core described by Mr. Walker has been given up in the Phœnix machines for some time.

Lightning Conductors at the British Association.—The Organising Committees of Sections A and G of the British Association have arranged a joint discussion on "Lightning Conductors," to be held at the Bath Meeting in September. Mr. W. H. Preece, F.R.S., will open the discussion, and Prof. Oliver J. Lodge, F.R.S., will defend the position he took up this year before the Society of Arts.

Folkestone.—Folkestone still seems to be *in statu quo* as to the electric light, although agitated in the desire to have the new illuminant. At the meeting last week Alderman Dunk seemed to fear that a committee would be appointed, which would make what contracts it pleased, and spend what money it liked. The Town Clerk said in any case the agreement would be a provisional one, and that nothing could be done unless the Town Council did it. It was mentioned that the utmost they could go to was to the limit of a shilling lighting rate.

"Journal" of the Society.—The new number of the *Journal* of the Society of Telegraph-Engineers and Electricians has been issued, containing the paper on "Fire Risks," by Mr. Preece, and Mr. Crompton's reply to the discussion on his paper on "Central Station Lighting." Sir William Thomson's paper on "New Standard Measuring Instruments" is also given, with illustrations. Prof. Silvanus Thompson's able and interesting historical paper on "The Influence Machine, from 1788 to 1888," is given in full, with illustrations of the various type of influence machines from John Canton to Wimshurst.

Electric Signals for the Army.—The introduction of Bruce's balloon-signalling apparatus has apparently given the idea that similar signals can be transmitted by hand while on the ground with advantage by army scouts or signal officers. Six small incandescent lamps are carried in the knapsack, with bulbs of different colours. A battery is also carried in the knapsacks, together with a very small electromotor, by means of which the tiny lamps can be elevated high in the air. The current can then be turned on, and by use of the various colours signals can be transmitted, and conversation can be carried on at night over long distances.

Medical Electricity.—Greater and greater attention is being paid to the use of electricity in medicine. Mr. W. Lynd, M.S.T.E., who has lately removed to Faraday House, Richmond Hill, Bournemouth, has performed successfully the process of removing fibroid tumours electrically. A paper has lately appeared in the *Lancet* on the use of electricity, by W. S. Playfair, M.D., F.R.C.P., Professor of Obstetrics at King's College, strongly advocating its more extended use. The growth of medical opinion in this direction is remarkable. We recollect hearing Dr. Royston-Piggott, F.R.S., a very well-known physician in his day, now better known for his valuable contributions on microscopy and astronomy, having said that he ran great danger of being plucked in his examination for his known belief in the virtues of electricity, and was advised to drop it for a year if he wished to pass. It is still his belief that this offers the most promising field for young medical practitioners. Several papers embodying this subject are to be read at the Glasgow meeting of the British Medical Society to be held this month.

Telephones on Trains.—Sir Edward Watkin, it is said, intends offering a prize of 100 guineas for the best solution of the problem of telephoning on trains between passenger and driver, or between passenger and guard. He

Digitized by Google

has been trying for some years to do this, and believes it to be the true solution of the problem of proper communication. "Of course," Sir Edward is reported as saying in a special interview with the *Pall-Mall*, "there are many difficulties—vibration and so on; but in my judgment there is nothing that cannot be overcome. If it could be done, that would be a revolution. When an old woman feels she can talk to the guard and her conversation will be registered by the telephone company—we should have to carry telephone boys on the engine or in the van—she feels it a comfort; she is no longer, as she fancies, between a certain person and the deep sea. At present, of course, it would not do to stop a train because a man thinks the carriage is shaky when it is perhaps only his nerves. With a telephone he could talk away, and properly explain whatever he wished. That is one of my pet projects, and another is the electric locomotive."

Long-Distance Telephoning. — There are signs already that the long-distance telephone will eventually cut out its older rival—at least, in many fields. A contest was lately arranged in New York for a ten minutes' reporting trial between telegraph (with transcriber of the notes) and telephone (with type-writing direct), and the telephone came off a very good second indeed, not much difference being between them, and a further trial was to come off. Long-distance telephoning has passed beyond the experimental stage, and has become an assured success. The long distance line is now complete between Paris and Marseilles, and a long-distance line is being built from New York to Chicago. One proof of the usefulness of the system is shown by the fact that the only communication between New York and Boston during last winter's storm was by a long-distance telephone. A net-work of telephones is being gradually extended over England; Glasgow is connected with most of the neighbouring towns, and it is intended to connect London with Bath and the West of England in this manner through Swindon. Verily, we shall soon be able to talk and write direct to the ends of the earth.

Cheap Electricity.—If the statements reported as having been given by a Swedish gentleman, Jonas Venstrom, of Orebro, are accurate, the useful service of electricity is extraordinarily cheap in Sweden. The following is what is said to be the state of affairs in Orebro, a town of some 40,000 inhabitants. The annual charge for a telephone is 17s., and for this charge the subscriber has a range of 100 miles from his home. In the city of Stockholm there are 7,000 subscribers, and every subscriber has his own instrument. The telephones there in use are made by the Erickson Company, of Stockholm, and are said to act much better than those in use here. At any rate, Mr. Jonas Venstrom says they can send a message with greater clearness a hundred miles in Sweden than we can from the suburbs of our towns. Electric lights are quite common, and the charge for an arc lamp is only about twenty-five shillings a year. Someone has said that the English invent and the Americans use the inventions. It seems from this that the Americans and English invent and the Swedish use them. However much we may long for the time, it will not be just at present that we shall be able to obtain a telephone and an arc light for a couple of guineas a year. This is where patent rights come in.

Atlantic Cable Tariffs.—At last the Commercial Cable Company has obtained a well-earned triumph, and from September 1st the tariff per word across the Atlantic is to be one shilling. Of the tactics of the combined companies the less said the better, but the facts may be recorded. When the Mackay-Bennett combination laid its cable, efforts were made to induce them to join the pool. So far as we can gather, these efforts at an agreement failed because there was no reality in them. The pool then put on the screw, saying agree to our terms or we will fight. They fought. The sixpenny tariff was a "fighting tariff." It was spoken of as such, boasted about as such. Result: no dividends to the shareholders and no "prostration in fear" from the Commercial cable. The fighting tariff failed, and then it was dubbed euphonistically as an experimental tariff, one that was fairly and squarely tried as an experiment to see if the increased messages would recoup the loss from tariff. In other words, being worsted in the fight, a happy thought suggests the calling it "failing in experiment," and now the terms long since suggested by the Commercial have been adopted. The telegraphing public were the gainers during the period of the "experiment," and now we trust to see a permanent settlement of the squabbles and a greater attention to the development of real business.

The Maxim-Weston Company.—The longest lane has its turning, and no doubt the resignation of Mr. Hugh Watt, M.P., will be a turning-point for better or worse to this company. The late chairman, according to his own ideas, took up the company when it was *in extremis*, and has carried it on, more or less successfully, with or without co-directors till quite recently, when the hubbub of revolt among the shareholders became too great for Mr. Hugh Watt to withstand. Years ago the present writer had several long conversations with Mr. Maxim and Mr. Massey, and heard their views upon the management of the company, and since then he has watched with some care the progress of the Maxim-Weston Company. It may surprise many to know that Mr. Maxim came over to England under an agreement with the company, which agreement was broken, or, at any rate, not carried out, and so, instead of this inventor's talents being at the service of the company, they were rejected. Unable, under the terms of the agreement, to turn his attention to electrical matters, Mr. Maxim turned his attention to military guns, with the result of designing the well-known Maxim gun. We ask, in all seriousness, What has the Maxim Company lost by such a course of action—by the driving away out of the work of the company one of the ablest inventors of the age?

Bean-Feast.—On Saturday last the employés of Messrs. Immisch and Co., electrical engineers, of Kentish Town, celebrated their sixth annual summer excursion. The party, to the number of about 85, left London in three four-horse brakes about eight o'clock, and after a pleasant ride arrived at Rickmansworth about 11.30. The head-quarters were The Swan Hotel, and after partaking of refreshments, they adjourned to a meadow for the purpose of indulging in a friendly game of cricket between the married and single members of the firm. After a most pleasant and closely-contested game, the singles, under Mr. Price, were accorded the victors over the married, who were led by Mr. C. F. Quicke, by 15 runs. The hour for dinner having arrived, all did ample justice to the excellent viands placed before them by the worthy host (Mr. W. Large). After dinner the usual toasts were proposed, among them being "Health, wealth, and prosperity to the firm of Messrs. Immisch and Company!" which was drunk with three times three and musical honours, the chairman (Mr. C. F. Quicke, manager to Messrs. Immisch)

Digitized by Google

remarking that the way in which they had drunk the health of the firm showed the unanimity which existed between employer and employed. A pleasant stroll was followed by tea, with toast and song, and the party returned about eight o'clock, having spent a most enjoyable day.

Cost of Electric Traction.—It has been aptly pointed out that if the tramway companies could see but a clear saving of one farthing per car mile only on their present cost of about 5d. per car mile, it would be worth their while to operate by electricity, for that saving would represent an increased dividend of two per cent. What, then, is to be said of the cost of the Richmond Electric Railway, a description of which we are giving in our columns? The entire operating expenses chargeable at the central station for twenty cars, with the present mileage, on the heaviest section of the track, is only two cents—that is, one penny—per car mile. This includes electrician, engineers, firemen, dynamo men, all coal, oil, waste, water, lighting and depreciation; the working force being, with the exception of one man, sufficient to handle forty cars instead of the present twenty. When the forty cars are in operation the expense will be reduced to about 1½ cents—that is, three farthings—per car mile run. Of course these figures are American, and may not be exactly paralleled in England, much more in London, where many incidental expenses are very heavy. But the item is suggestive enough to allow a considerable margin for such incidentals, and yet to show a very great increase of profit. We shall be expecting, after consideration of the concrete and practical instance now before us, that English financiers and tramway managers will begin to appreciate the capabilities of the electro-motor.

Bath.—The following editorial remarks in last week's *Cheltenham Examiner* will be read with interest:—"Bath has taken precedence of Cheltenham in the adoption of electricity for street-lighting purposes. At a meeting of its Town Council it was determined, by a majority of nearly two to one—22 to 12—to accept the tender of Mr. H. G. Massingham for the lighting of a large area of the city, and including its central and principal streets, for a period of seven years. The conclusion thus arrived at has not been reached without much and animated controversy, and it marks the triumph of intelligent enterprise over almost every form of obstacle that interested opposition could devise. The exact system of electric lighting adopted is of minor importance compared with the general effect of the decisive step taken. . . . The members of the Electric Lighting Committee of the Cheltenham Corporation recently had an opportunity of inspecting the installation at Taunton, under Mr. Massingham's personal direction, and the adoption of the same system at Bath endorses the favourable opinion our representatives formed of it. In some points of detail the installation at Bath will doubtless be an advance upon that at Taunton; but, in any case, the fact that a city of the importance and position of Bath has declared for the new illuminant is likely to exercise a marked influence upon the development of electric lighting in the provinces. Even Cheltenham may not be afraid to follow a lead that Bath has so spiritedly taken."

Electric Lighting in Scotland.—Mr. Rankin Kennedy, of Woodside Electrical Works, Glasgow, has recently completed installations of electric light on the following steamers:—The "Smith" and "Cass," two passenger ships, built by Messrs. R. and W. Hawthorn, Leslie and Co., Limited, for the Formosa Trading Co., China; the s.s. "Tynesider," owned by the Tyne Steam Shipping Co., and trading between Newcastle and London; the "Paula" and "Caucase," two oil-carrying steamers, built by Sir W. G. Armstrong, Mitchell and Co., Limited, Walker Shipyard; the "Trieste C," a small passenger steamer for the Adriatic, built by Messrs. Wm. Simons and Co., Renfrew; and the "Leon y Castilio" and "Vera y Glavojo," two steamers built by Messrs. D. J. Dunlop and Co., Port Glasgow, for the Canary Islands passenger and goods' trade. In addition to the above, the firm have now on hand three steamers, the "City of Oxford," "City of Cambridge," and "City of Calcutta," for the "City" Line of Messrs. G. Smith and Sons, Glasgow; two large oil-carrying steamers for Sir W. G. Armstrong, Mitchell and Co., Limited, and a number of other shipping and land installations of considerable importance. Mr. Kennedy has now completed, and is using exclusively for ship lighting, his double-cylinder single-acting engine. It is being very favourably received, and, we understand, is giving universal satisfaction; where direct driving is desirable, it is specially applicable. We hope shortly to publish a full description and results of tests of this engine.

Converts to Electric Tramways.—It will be noticed that we give continually, week after week, notices of the spread of electrical traction for tramways in America. It is impossible to follow the evolution of electrical traction in England without taking into account the great developments perceived in this department in the States, and persons in authority discussing the relative advantages and objections to the new system should realise that the phase they are passing through has been passed through in America, and that they cannot do better than learn from that experience. In America, twenty-eight cities have adopted the electro-motor for their streets, and over fifty more are investigating its merits with a view of adoption. The American technical press are just now jubilant over the conversion of Mr. Henry M. Whitney, of the West End Railway Company of Boston, to the merits of electric traction. Mr. Whitney's company were intending to put in a cable system; but, after examination of the Richmond electric road and that at Alleghany city, and after seeing with his own eyes what electricity can do, he is a thorough convert to the new system. "I believe," said Mr. Whitney before a Special Commission of the Brookline Board, "that the electric motor at this day has reached that stage of development which makes it a perfectly practicable working machine, superior in all respects to horses for quick transportation," and he goes on to point out its advantages also over the cable. "Such evidence as this from the outside," adds the *Electrical World*, referring to this speech, "is not to be gainsaid. It is simply the recognition by a leader in the world of finance and commerce of the claims that have been made by electricians, and every month will give it greater weight and validity."

Armature Protectors.—A special cut-out for the protection of armatures of dynamos is being introduced by Mr. Charles D. Wright, of Petersburg, Illinois. It is designed to throw a suitable amount of resistance into the circuit when the current therein becomes abnormal, and before the regulating devices connected with the dynamo can act, to protect the armature of the machine from being burnt out. Says Mr. G. E. Fish, electrician to the Chicago Arc Light and Power Company, with reference to this invention: "I have had a good deal of experience in connection with the practical operation of electric

Digitized by Google

light stations, and consequently know the liability of even the best and most thoroughly insulated machines to occasionally burn out their armatures. I have therefore taken a good deal of interest in the protector, and in giving it a protracted and thorough test. I have now had the instrument up and in position three weeks, and have watched it closely during that time. I have frequently short-circuited the entire number of lights on the machine, thus putting the protector to its fullest test. As everybody at all familiar with the operation of electric light machinery knows, the short-circuiting of a machine in this manner would mean sure destruction of the armature without the protector. With the test I made, however, using the protector, the short-circuiting had no effect whatever on the running of the machine. The machine ran right straight along without the slightest disturbance, thus proving conclusively that the protector does just what is claimed for it—namely, absolutely protects the armature from injury when the machine from any cause becomes short-circuited. I cannot too highly endorse the armature protector, and I certainly think, and would recommend, that every dynamo in use should be protected by it."

Founders' Shares.—We have repeatedly pointed out, says the *Citizen*, what has been rarely noticed elsewhere, that companies started with founders' shares are intended to pay promotion money to an enormous amount. The holders of £1,000 of the capital of the Metropolitan Electric Supply Company are to take one-half of the profit earned by the remaining £499,000 beyond 7 per cent. If the company earns 10 per cent. per annum, its shareholders will have to pay away £7,500 a year to its promoters or their representatives, whose utmost outlay for preliminary expenses or risk of any kind in the adventure may not have exceeded £10,000. To make the arrangement at all a fair one for the other shareholders, the founders' shares ought to be cancelled when they have received altogether a fixed sum —such as, let us say, twice or three times the amount paid for preliminary expenses. If these had been the terms upon which the Metropolitan Electric Supply Company had offered its capital for subscription, it would have seemed a promising speculation. As it is, although it has already been, and doubtless will continue to be, vigorously written up, and its shares will doubtless for a time command a substantial premium, the cautious investor who has not been in a hurry to apply for them will bear in mind that many other opportunities to take shares in electric supply companies will probably occur. There will be no such monopoly in the future for electric lighting as there has been in the past for gas, and the quotation of the prices of gas companies' shares which the prospectus gives has really not much bearing upon the question of probable dividends for the shareholders of the Metropolitan Electric Supply Company. It has also yet to be proved that electricity can be supplied "at rates which will attract customers, and be remunerative to the company." So far, electric lighting has been a luxury for those who can afford to pay at least twice as much as for gas.

Restrictions of Telephones in England.—Some surprise has been expressed from time to time at the small amount of general use of the telephone service in London as compared with some other countries. Two points militate against its more extended use in London. One of these is the high charge for rent of the telephone, the usual price of twenty pounds a year being quite prohibitive for the common use of the middle class residence, such as is common in some towns in the States, where the lady of the house uses the telephone for all and sundry messages. She makes her morning calls by its means, orders her groceries and other necessaries, and embarks on a long chat with her dress-maker. She is in communication with her husband, her doctor, the police, and the fire-office. This extended use of the telephone will not come about until the usual charge is much reduced, say, to two or three guineas a year. It is possible that with co-operation of several of the inhabitants of the same place combined with pecuniary allowance from shopkeepers to those customers using the telephone (in return to saving of messengers), that a reduced rate might become more general in the suburbs of London without a reduction from the telephone companies. This has been done, we know, in a few cases, and the method is worthy of imitation. One enterprising shopkeeper, in combination with others, might obtain the use of the telephone for his customers, and save a vast amount of the trade now going to the Civil Service Stores by such means as this. The other reason for the restriction of the telephone applies to City life. It consists in the comparative cheapness of messenger lads in London to that in America. Any number of lads can be obtained for a weekly wage of from four to five shillings—equal to one dollar—a week, and while this is the case it pays City houses and companies to employ a staff of lads to continually take their messages by hand, rather than to pay for the use of a telephone. The service is quick, intelligent, and has the advantage that packages, as well as messages, can be sent. In America, except in the near East, the case is often quite different. Men, or even lads, are difficult to obtain at all as mere messengers, except at what would be prohibitive rates, and therefore the telephone performs this function with great profit.

Weston's New Alloys for Electric Conductors. In seeking for a means of obtaining a conductor having a constant resistance at all temperature, says the *Electrical World*, for use in electrical instruments, resistances, &c., Mr. E. Weston has recently discovered two new alloys which accomplish the desired object. He has discovered, in the first place, that the metal manganese imparts a very high electrical resistance, and, in fact, a higher specific electrical resistance than can be obtained by the addition of any other metal to alloys, into which it enters as a constituent; and, second, that the addition of the manganese has the further remarkable property of rendering the electrical resistance of such alloys nearly or quite constant under varying conditions of temperature. Thus an alloy of manganese with copper produces a conductor having the above characteristics. This alloy is made by the common process of melting the two metals; but in practice Mr. Weston employs ferro-manganese on account of its greater cheapness, and this he mixes in the proportions of copper, seventy parts; ferro-manganese, thirty parts or thereabouts. This alloy is capable of being rolled and drawn, and is made up into wire in the usual way. The exact proportion of the metals used may vary somewhat; but while Mr. Weston has found that the addition of manganese or ferro-manganese in any proportion to copper is an advantage, so far as preserving a constant resistance is concerned, he finds that the best results are obtained by the use of the proportion given above. Mr. Weston has also discovered an alloy, the resistance of which is lowered by an increase in tempera-

Digitized by Google

ture, a property heretofore lacking in metallic conductors. This alloy, the resistance of which lowers with increase of temperature, is composed of copper, manganese or ferro-manganese and nickel. This may be used for one portion of a coil and copper or german silver for the other, so that should the coil be heated by a current, or otherwise, the changes of resistance in the two portions of the coil will neutralise each other. To secure an exact balance is a matter easily determined by adjustment of the lengths of the two portions of the coil, or by the relative proportions of the metals used in the alloy. Mr. Weston employs with german silver or copper an alloy containing from sixty-five to seventy parts of copper, twenty-five to thirty parts of ferro-manganese, and two and one-half to ten parts of nickel.

Prof. Gray's Telautograph.—The daily press are going wild over another discovery. This time it is Prof. Elisha Gray, not "Prof." Edison. We have heard rumblings of a wonderful development of this instrument for telegraphic transmission of a person's writing—which, by the way, is named "telautograph" (meaning "own writing to a distance"), and not "tetantograph," as the *Daily News* and *Pall Mall* originally had it. No details are to hand except that the instrument consists of a transmitter and a receiver, and uses a pulsatory instead of a variable current. The invention is reported to work so accurately and rapidly as to give promise of being commercially successful. It is a pity that some circumstantial details are not cabled over, besides the mere statement that it has been done. If Professor Gray or Edison were suddenly to announce that they had succeeded in inventing an instrument to telegraph to the moon—giving no details—the Press would, no doubt, immediately commence to "boom" the thing. However, from what is stated, the inventor has lost no time in interesting capitalists, and in attempting to get to work. The following are the latest particulars as given by the New York correspondent of the *Daily News*:—"An immediate effort is to be made to apply Prof. Gray's new invention, the telautograph, to commercial uses. The Judge of the Circuit Court of Richmond, Virginia, has just granted a charter for the purpose of working the invention. The charter is granted to a company the general objects of which are declared to be "to promote, establish, and maintain the general business of a telegraphic, telephonic, and telautographic company within and throughout Virginia and other States and Territories of the United States, by the use of electrical or other devices suitable or applicable to the same, and particularly by means of what is known as the telautographic system, invented by Prof. Elisha Gray, for the transmission of messages or other communications written out in ordinary script, or otherwise suitably prepared for such transmission, and the automatic reproduction of the same at the office of destination, including any extension or improvements of the said system hereafter devised for or added to the said telautographic system, and any other telegraphic or telephonic device to be used in conjunction with each other or separately, as may be found expedient, and any other methods of electrical intercommunication to be used if desired." The charter further authorises the purchase and use of lines, poles, and wires, fixtures, stations, exchanges, or other facilities, including submarine cables, to work the system. The capital of the company is not to be less than 500,000dols., nor more than 15,000,000dols., divided into shares of 100dols. each. The company may hold 10,000 acres of land in each of the States and Territories. The principal office will be in Richmond, with branch offices where needed. As soon as 600,000dols. are subscribed the company will commence business. Some of the largest capitalists in the country are said to be interested in the enterprise."

E.P.S. Catalogue.—We have received a new edition, dated July, 1888, of the Electrical Power Storage Company's catalogue of accumulators and fittings. The book is very handsomely got up and fully illustrated, containing detailed particulars of the company's manufactures arranged and tabulated in order, comprising the "E.P.S." accumulators in great variety; ordinary types for lighting or general purposes, special types for tramcars, railway-carriage lighting, telegraphic work, medical work; also all accumulator necessaries, switches for one up to a thousand amperes, automatic regulators and cut-outs for use in central stations, measuring instruments for use with accumulators and main switch-boards, with detector, hydrometer, and other necessary apparatus. We notice a special form of hydrometer Hick's patent, consisting of a flattened tube, with bent end to hang on the edge of the glass cell. The tube is perforated to allow free circulation of the battery solution, and small glass globules, coloured differently, are contained within the tube; these rise or fall at certain distinct specific gravities, and the condition of the liquid can thus be very readily observed. Several ingenious automatic regulators and alarms are illustrated; in that for train lighting a soft iron coil attached to the switch lever reduces the number of cells on increase of current to avoid over-incandescence of the lamps. Automatic bells are shown which give an alarm when the cells are discharging above their normal rate. A modification of this apparatus, instead of ringing a bell, is arranged as suggested by Messrs. H. Lea and Thornbury, so that a resistance is alternately switched in and out, causing a pulsation of the light, which can only be rectified by reducing the number of lamps until the current does not exceed the normal rate of discharge. A special department is included for hire of fully-charged batteries for temporary lighting at a price equal to one shilling an hour for six hours, for a battery giving 22 amperes. With a view of giving customers the full benefit of the latest type of cells an exchange department is arranged with special prices for complete exchange of old type plates for new ones, utilising wherever possible the original glass boxes. Special insulators for erection of the sets of storage batteries are illustrated; these are glass insulators of mushroom shape, standing in a strong cup of non-evaporating oil. These effectually prevent leakage from the base of cells. For cells where the plant is required to work automatically, or for considerable periods without inspection, such as for tram work, launches, or railway lighting, a special form of celluloid separator is provided, the use of which removes all possibility of short-circuiting. We are very pleased to see the constant and varied improvements which are made by the Electrical Power Storage Company in their batteries, not only in minor details, but in special forms to meet the various applications required. The progress gained is not only to be seen in the greater adaptability of the various types, but is making itself felt in the large increase of life of the batteries. The considerable increase in the allowable output of the new types of cells—close upon half as much again—is a most material gain, not only in reducing the weight where the cells have to be carried, but in diminishing in corresponding ratio the first cost of batteries for a certain output. Illustrations of the application to electric launches and to tramcars are also given in the catalogue.

ELECTRICAL ENGINEERS.

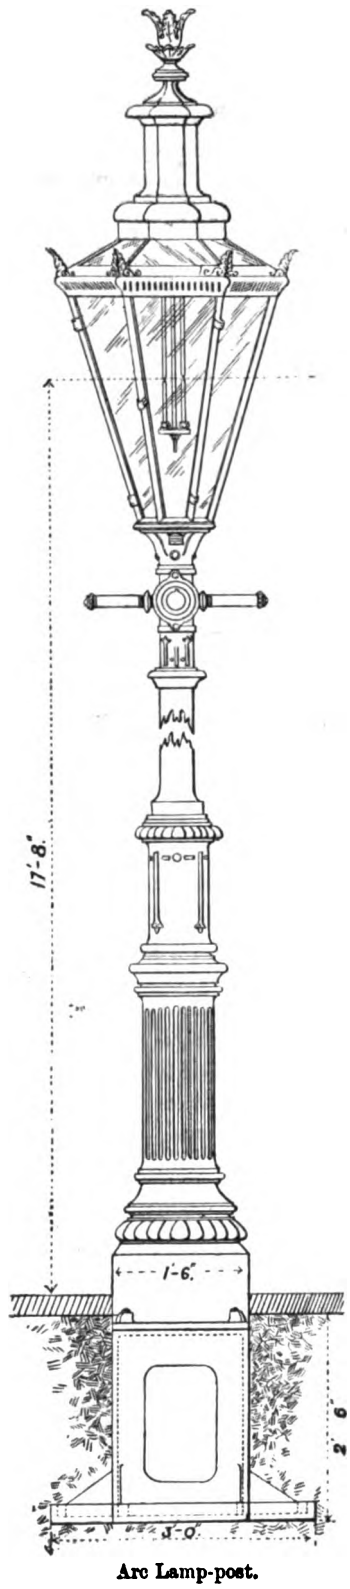
II.—THE ANGLO-AMERICAN BRUSH ELECTRIC LIGHT CORPORATION, LIMITED.

One of the largest and best-equipped electrical engineering concerns at present in existence in England is that of the Anglo-American Brush Electric Light Corporation, of Belvedere-road, Lambeth, S.E. This company, which was originally formed, as is well known, to carry out the inventions of Mr. Charles F. Brush, of the United States, and which has effectually familiarised English people with this method of arc lighting, known as the "Brush" system, has for a long while extended its operations beyond those of the Brush patents, and now embraces in its inventions and manufactures practically the whole field of ordinary electrical engineering. Besides the complete system of Brush arc machines and Brush arc lamps, this corporation has specialities for the well-known Victoria incandescent dynamos (low tension system) and the Victoria incandescent lamps; low tension arc lamps, for parallel working on incandescent circuits; the Mordey alternating-current generator and transformers; constant-pressure dynamos, for train lighting; special dynamos for utilising windmill power; search-light projectors, for naval and military use; Raworth's combined friction-gear plant, for incandescent stations; Brush direct-driving plant; electro-motors, working from 2 h.p. up to 100 h.p. and over; and special electric tramway apparatus. We have recently taken an opportunity of visiting the works, and of ascertaining the methods of business adopted by the corporation, and at the present time of prospective development are glad to be able to give so good an account of their business.

While recognising the extreme importance of securing the best and most successful means of dealing with the technical part of the electrical engineering problems, the management of the Anglo-American Brush Corporation have felt that if a company such as theirs is to deal successfully with the vast extensions of electrical work which are soon to come before the world, a sound commercial basis, both as between themselves and others, and between their own employees, is not less necessary to final success. One of the points, therefore, that they have kept prominently before them is to arrange the whole of their business transactions on a thoroughly commercial basis from exactly the same outlook as any other large engineering enterprise. Besides this, they have taken trouble to introduce several features which will tend to make the whole of the organisation work together with ease and with mutual benefit. For this purpose an arrangement has been made whereby a portion of the net profits of the company, a certain per cent. of the dividends, is set aside for distribution, in proportion to their salaries, among such of the officers who have been nominated by the board as participants. Anyone is eligible to be nominated who has been a servant of the corporation for a certain period, and has not contravened the rules of the scheme. The interest of the staff is thus made identical with that of the shareholders, and a considerable economy is effected in a number of small things which it would be perfectly impossible for the heads of departments to control. The system has already produced very gratifying results. A further step in this direction has been the establishment of a sick benefit club, founded entirely by the workmen and the officers and directors working together, the workmen contributing a small amount voluntarily out of their weekly earnings to provide a sum in case of sickness. There are close upon 200 subscribers to this club, and the reserve fund already amounts to a considerable figure.

The corporation have likewise tried to take a long-sighted view of the extension of the electric lighting industry, believing that the benefit of the whole trade will result in their own continued prosperity. The corporation have, therefore, devoted a large amount both of time and trouble to such questions as the amendment of the Electric Lighting Act, an immense amount of work for which has been done in their offices, the chairman of the corporation—Lord Thurlow—introducing and carrying the Bill in the House of Lords. Again, there is the Electrical Trades Section allied to the London Chamber of Commerce. The initiative which has lately resulted in practical action was largely due to the energetic manager and secretary of the corporation, Mr. Emile Garcke.

For the training of competent electrical engineers and workmen the corporation have long introduced a system of pupil training and apprenticeship for the proper training of skilled electricians, and have always eight or ten apprentices on their way through the various departments.



Arc Lamp-post.

The purchase-hire system, as applied to electric lighting plants, was also a very advantageous innovation introduced by the Anglo-American Corporation. During the present more or less depressed state of trade there are many establishments having no great amount of capital to spare, who have been enabled to increase the usefulness of their factories without any necessity for immediate large expenditure by adopting the system of payment. It may also be noted that the reclassification of railway freights, by which a large saving is annually effected by firms engaged in the

Digitized by Google

electrical trades, was largely due to the efforts of the Brush Corporation.

The prevailing object in the management of the Corporation's business, during recent years, has been that of economy; and so thoroughly has this principle been adhered to that, although the volume of their transactions is now nearly three times greater than it was five years ago, the expenses of management have been reduced by over 40 per cent. This result is the more remarkable when it is borne in mind that a great deal of the Corporation's work in the past has not been done in the hope of immediate profit, but rather to improve their position in view of the revival of the business, and to pave the way to the extension of operations.

With these remarks as to the manner in which the Corporation have addressed themselves to promoting the development of the electrical industry in this country, we will now proceed to give some description of the works and manufactures carried out by this company.

The Works.

The works of the Anglo-American Brush Corporation occupy extensive premises, situated in Belvedere-road, Lambeth, near Waterloo Station, and just over the Charing Cross foot-bridge. Passing first through the general offices, where the whole of the commercial part of the business is carried on, and in which the board meetings take place, we come to the drawing office, where a number of draughtsmen and designers are constantly engaged, nearly every estimate sent in or contract received necessitating some amount of designing work or illustration.

Engine Power.

The engine power used for running the works is separate from that used in testing dynamos. The works' plant consists of two Galloway boilers, supplying steam for the Galloway horizontal stationary engine, indicating up to 150 h.p., which drives the lathes, drilling and shaping machines, and other machinery in the works. Two Fowler multitubular semi-portable engines are used for testing the dynamos and motors before being sent away, or for any similar auxiliary work.

Machining and Fitting Shop.

The machining and fitting shop occupies the whole of the ground floor, and in this the work of shaping, turning, planing, and drilling the heavy parts of dynamos and other electrical apparatus is in progress. We see here on one shaping machine, eight sets of huge magnets, 10in. diameter of forged wrought iron, simultaneously shaped and slotted for the large 60 unit dynamos now on hand. Drilling and shaping machines are busy all around; in the corner are stamping machines stamping out pieces of copper, and metal cutting machines slicing up rings of solid copper tube into segments of the required size for use as commutators on the large Brush arc dynamos. These are all made to gauge, so as to be readily interchangeable. Further along we see the bevelled pieces of copper, arranged in numerous series on a ring, ready to be formed into the Victoria commutators. This, though composed of dozens of separate strips of copper, each separated by its mica insulating sheet, with no metal to metal, and without ordinary opportunity of mechanical joint, is yet bound together entirely by hand till it forms one block, perfectly smooth and true, and as solid as a single piece. The copper bars are rolled true, just touched up with the file; the double piece for connections is tinned, soldered, and then riveted thereto, and the end soldered to the armature wire and turned over.

A "Brush" engine, designed by Mr. Raworth for use with Brush dynamos, described later on, and Raworth's rope gearing is being fitted up. This latter is the form of gearing for use with ropes instead of belts for transmission of power, which has been adopted with advantage in some cases by the Corporation. A stout rope passes continually eight times round the driving and driven pulleys, crossing in one guide pulley; this does away with all special tension on the ropes, and makes the whole run very quietly and evenly. Pulleys, bearings, belt tighteners, and other apparatus are also being manufactured.

Smiths' Shop and Furnaces.

To one side is the smiths' and foundry shop, where work necessitating the heating, welding, and melting of metals is carried on. In the same department are the furnaces used in the manufacture of the Brush company's "Victoria" lamps.

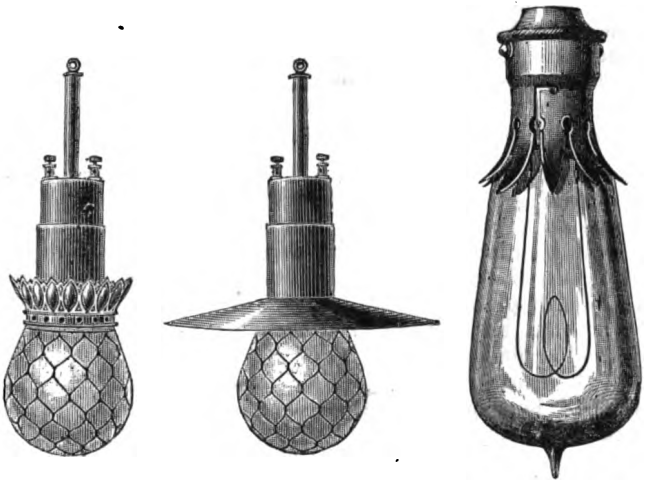
Dynamo Erecting Shop.

This is the name of the department where all the different parts of the machines are brought together from the various other departments, and are fitted and bolted together, connected up and finished off for use in electric lighting, &c. Here we see dynamos—arc and incandescent—and motors, large and small, being fitted together, or ready to be sent away. Some of the heavy dynamos for export are specially made to be easily taken to pieces by drawing four bolts. By this means the heavy magnets can be separated, leaving the magnet coils still connected. In the larger sizes, or for special transport, these can be still further disconnected, and by taking off the bearing caps the whole of a 500-light dynamo comes into parts, which can easily be lifted by a couple of men. One illustration of the strength of make of the Brush Corporation's Victoria dynamo is that of a 30-unit machine, sent to an overhill place in New Zealand. The carriage employed to transport one of the large and heavy magnets unfortunately overbalanced at the edge of a rocky gorge, and the whole was precipitated on the rocks below. Help was obtained, and the magnet fished up; the horse was quite dead, but the magnet was not, though it had bounded far away among the rocks. The machine is still working and doing its duty well.

Parts of the new Mordey Alternator are to be seen, and electromotors for hauling, pumping, and traction work are under progress.

Light Fitting Department.

Going up the lift, we come to the light-fitting shop on the first floor, where long rows of light lathes,



5 Ampere Arc Lamps. Victoria Incandescent Lamp.

power presses, drilling and stamping machines are occupied with the smaller parts of dynamos, and in the manufacture of arc lamps, lamp rods, brushes, switches, and other fittings. Here we see the celebrated Brush arc lamps (2,000 n.c.p.) in process of manufacture, the parts of which are made with the very greatest accuracy. The celebrated little Brush "clutch," by which the regulation of the Brush lamps is effected, about which there have been so many lawsuits in the United States, can be seen in process of manufacture, together with the metal brush connections for the lamps. Both of these are beautifully finished specimens of metal working, finished true, and lacquered to prevent rust, and all made on the interchangeable system. The inside electrical arrangement of these lamps is exactly the same as when first introduced from America, with the exception that the ratio of winding is slightly different to obtain a more sensitive feed, and the external appearance is somewhat different from the American type of Brush lamp. Otherwise, the lamp is practically unaltered, which speaks well for the perfection of the first invention.

The 5-ampere Sellon arc lamps are also greatly coming into favour, large numbers having been made for use on low tension circuits in parallel with incandescent lamps.

Digitized by Google

The appearance of these lamps is shown in the cuts both for public buildings where a moderate arc light is required, and for warehouses and shops.

Resistances for use in electric light circuits are made in this department. The use of platinoid wire, lately advocated before the Society of Telegraph-Engineers by Sir William Thomson, has been adopted for a considerable time by the Corporation, who have appreciated the property of this wire in remaining of approximately the same resistance at whatever temperature it may happen to be. Resistance frames are made up in a simple and fireproof form in cast-iron openwork cases, fitted with small porcelain insulators, and the resistance wire threaded through these. They are thus beyond possibility of setting fire to surrounding woodwork, and allow ample ventilation.

Winding and Pattern Shop.

On the top floor we come to the winding and pattern shop. The winding department is, perhaps, the most delicate operation experienced in the manufacture of dynamos, and necessitates clean and careful handling, and freedom from all metallic particles. It is, therefore, placed on the top floor, where only wood working is also carried on. We see here the various coils and armatures in process of manufacture; heavy shuttles of insulated copper wire being carried under and over the coils by hand, firmly pressed into place, and made as solid and as firm as possible. In the case of the cores of the Victoria dynamo, long continuous strips of rolled sheet iron are wound off one bobbin, a second bobbin feeding strips of special paper for insulation. For the manufacture of the cores of the Brush arc armature, similar long strips are taken, and stamped pieces of sheet iron are inserted at intervals, the continuous strip binding all into one compact body, to build up the peculiar-shaped armature used for these machines. The stationary coils of the Mordey Alternator are here wound and fixed on their places, and the winding of incandescent machine armatures and those for motors is carried on in like manner.

The pattern department is carried on at one end of the long room, wood work of all kinds being finished for models and patterns.

Testing Department.

Returning to the ground-floor, we come to the testing department. Here are fitted the two semi-portable steam-engines mentioned before, with lines of shafting and pulleys for testing the capabilities and output of the new machines. These will give a combined energy of 150 indicated horse-power, but by a special modification of the Hopkinson method a much greater power can be tested than these can be made to give. If a dynamo requiring several hundred horse-power is to be tested to its full capacity, it is connected by belts to the shafting, and measuring instruments are inserted in the circuit. The current which it generates is led to another dynamo, which is coupled as a motor, and a belt from that is taken back upon the shafting. When this combination is running, as much as two or three hundred h.p. can easily be thus transmitted to *the belt driving the dynamo*, which returns its energy by way of the motor to the shafting, the engine merely supplying the difference in friction and loss in conversion, and thus doing away with the necessity for very heavy engine power. Siemens' dynamometers are used in these tests, together with Ayrton and Perry ammeters and voltmeters, and Cardew's voltmeter. Thomson's mirror reflecting galvanometer, with a Wheatstone bridge, is used for more delicate tests for insulation and resistance. The use of a special instrument-room, quite away from the dynamos, has been found to be very inconvenient and more inaccurate than the method of testing adopted, which is to take tests with the instruments placed on movable tables, moving them about in different places, and taking several readings, reversing the connections, and thus checking the results, which are then always under the eye of the person testing.

For testing arc lamps there is an arrangement by which 80 lamps can be tested simultaneously. A platinoid resistance is also strung in wires overhead, the resistance of which, cold, is accurately known, and is without self-induction. This is used for testing Alternators. A resistance of several hundred incandescent lamps is used for testing incandescent machines, and special wire resistances of 10 ohms can be used in parts or connected in parallel for resistances of one-tenth or one-hundredth of an ohm.

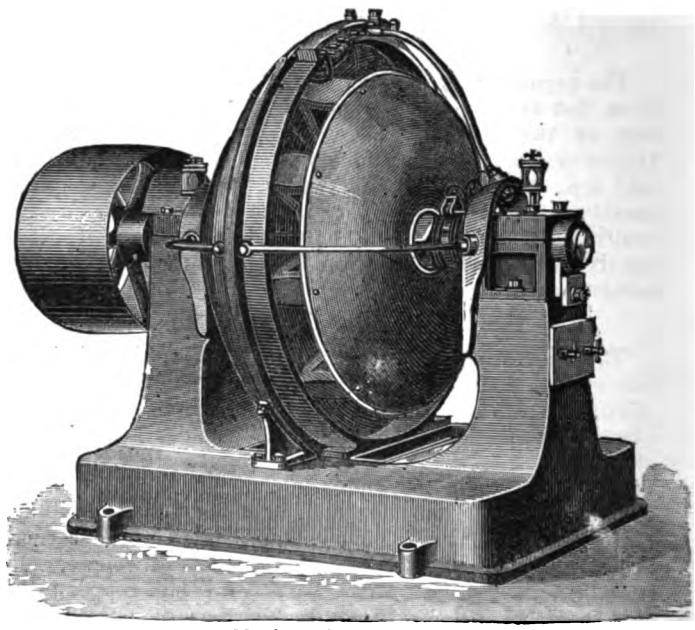
Incandescent Department.

A special department, in a separate building, is organised for the manufacture of the Victoria incandescent lamps. For eight years, since the inventions of Lane-Fox were first secured by the Corporation, the manufacture of incandescent lamps has been carried on even before the time of the invention of Edison's lamp, and the evolution and development of this lamp has gone on apart from that of other makers. A vacuum pump is used for assisting the exhaustion of the lamps, which is done by means of modified Sprengel mercury pumps, producing the nearest approach to a perfect vacuum attainable. The complete process, from the glass-blowing to the finish, is carried on in this department, preparing the filaments, mounting, sealing, and exhausting, the work being done mostly by girls.

A description of the process in its principal points was given in the recent trial, the lamps being made without any use of the Cheesborough process of "flashing" for standardising, the whole process being a development of the early manufacture of lamps under the Lane-Fox patents.

The Brush Dynamo.

This well-known machine is made in considerable numbers for all parts of the world. Dynamos for a total number of 8,000 arc lamps have been made for England since their



Mordey Alternator.

introduction. The usual large size of machine will supply 55 arc lamps, with 10 amperes of current each, at a total E.M.F. of 2,700 volts. Some idea of the strength of this current may be obtained when it is stated that one of these machines would light a 10 ampere search lamp (through properly insulated cable) at a lighthouse through 200 miles of No. 6 wire—that is to say, at 100 miles from shore. Smaller sizes of these dynamos are made for 10, 15 and 23 arc lamps.

The Victoria Dynamo.

This dynamo is also well known, and is for supplying current for the small incandescent lamps. It is compound-wound, being electrically self-regulating for any number of lamps from one to its maximum; or can be made to keep a constant pressure at a certain position at a distance, as might be required when water-power is some distance away, and allowing for a normal loss in the cable. The dynamos are made to supply from 15 to 1,000 16 c.p. incandescent lamps, and are in use on board ship, in public and private buildings, and for the various Governments all over the world.

The Mordey Alternator and Transformer.

This plant, which is a comparatively new feature of the Brush Corporation's electrical engineering operations, has

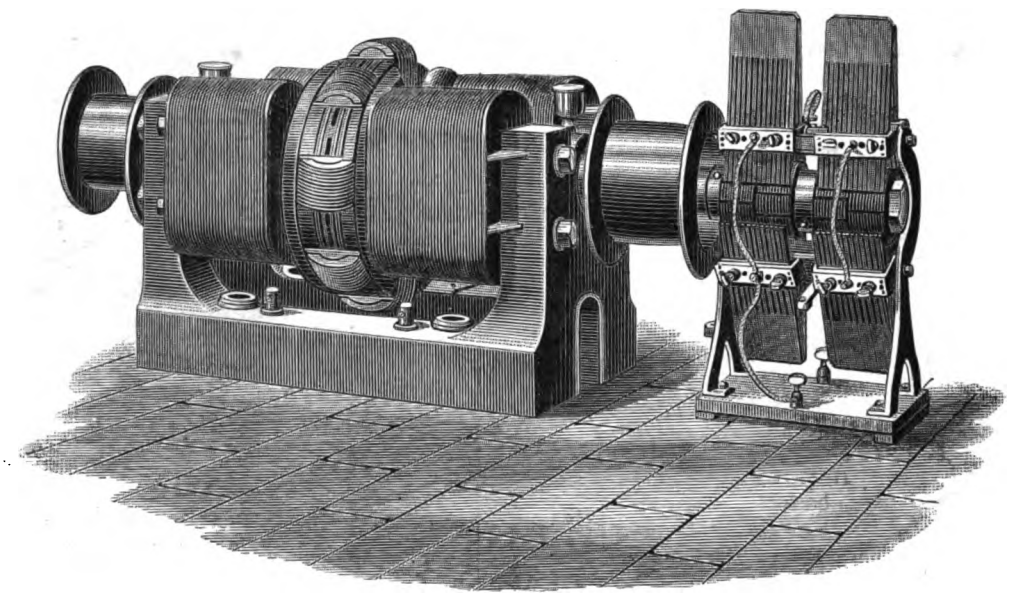
Digitized by Google

been described and illustrated in this journal for June 15, page 558, and consists essentially of the adaptation of strong mechanical arrangements for high tension alternate currents for use with transformers. The chief feature of this alternator is the heavy revolving magnet. If one imagines a huge iron mushroom, of which the stalk is wrapped with wire, and thus becomes one pole of a magnet, the edge of the huge mushroom-shaped ring being the other pole. This is cut into nine portions, becoming, of course, nine large south poles. The second mushroom ring consists of nine large north poles, and both these on one axle revolve rapidly past the induction coils. The coils, being the more delicate portion of the whole apparatus, are stationary. Each coil is separate, and can be disconnected by unscrewing four bolts and breaking the electrical joint. Each coil can be disconnected and taken out without otherwise disturbing the other parts of the Alternator. The first of these machines is at use at the central station in Black Horse-yard, Oxford-street, and a second is being made for the same place.

The Transformer is of a very simple form, recently illustrated in our columns Mr. Mordey considers it essential to the practical working of transformers that they should always be worked well within their limits, and thus require no attention. Those in use at the above-mentioned station are simply locked in a small compartment, and have not required the slightest attention since fixing.

Train Lighting.

The lighting of trains by means of a dynamo fastened to the axle has been effected now for some years with the use of Brush dynamos of a special make. The dynamo used has not, as far as we know, been illustrated hitherto, and we give herewith an illustration of it. It is an ordinary Brush arc dynamo wound in a special manner to give a constant E.M.F. at all speeds. There are two sets of brushes on each commutator, one set connects automatically when the train is travelling forward, and the other set when on the reverse journey. This arrangement has been in use on the London, Brighton and South Coast Railway, and also on the Great Northern Railway.



Brush Train-Lighting Dynamo.

This, by means of a governor-ball arrangement, completes the circuit when the train has attained the speed of 10 miles an hour, and from that speed up to the quickest of 50 or 60 miles an hour, the pressure is practically constant, the current only increasing, without any automatic device except the first cut-in. When the lamps are turned on they are fed direct from the dynamo, the excess going into a set of 26 accumulators kept in a locked compartment of the guard's van. These feed the lamps when the train is at a standstill, and in operation the arrangement requires no supervision, the whole being perfectly self-acting. An illustration of the perfection of the electric regulation as the speed increases was obtained some little time ago very forcibly, by a wrong pulley having been inadvertently put on by the railway company. The guard did not notice anything until the full speed began to be obtained, when the dynamo began to hum with the excessive speed, attaining a speed of, perhaps, 3,000 revolutions per minute, and causing the guard some fear for his personal safety. But the pressure did not increase, and nothing wrong was noticed at the lamps, nor anywhere except the extraordinary speed of the dynamo.

Windmill Lighting Plant.

For many years there has been talk of deriving power from windmills, and storing the energy by means of accumulators. The Brush Corporation, in the summer of 1887, carried out an installation on this principle. This was for the Duc de Feltre, acting, we believe, partly on behalf of the French Government at Havre. The plant consisted of two special Victoria dynamos, arranged with automatic circuit closers. One of the dynamos started, when a speed of 120 revolutions was attained, and continuing to 400 revolutions. The second one then took up the running, commencing at 400, and going up to 750 revolutions a minute. At the higher limits of speed there was an electrical cut-off for each dynamo, and a striking gear enabled the attendant to stop the armature revolving. The regulation of the dynamo itself varied the strength of field to suit the altered conditions of speed.

Mr. Mordey made some actual tests upon the spot, in concert with some representatives of the French Government, one of whom was the engineer to the electrical and engineering departments of the coming French Exposition of 1889, another being the Duc de Feltre. The tests showed an efficiency of over 90 per cent. of the power absorbed from the windmill. The E.M.F. was 75 volts, and the current varied from eight amperes at 120 revolutions to 160 amperes at 650 revolutions.

Ship Fittings.

A very large number of ship fittings are made and fitted by the Brush Corporation themselves. Mr. Raworth has had large experience with this kind of work, and has designed many fittings for ship work, overcoming the difficulties which were first experienced in procuring thoroughly satisfactory fittings for use on board ship. The Brush Corporation have made ship lighting one of their special features, having fitted a large number of the great liners and English and foreign men-of-war, including a very great number—in fact, the greater proportion of those fitted—of torpedo boats.

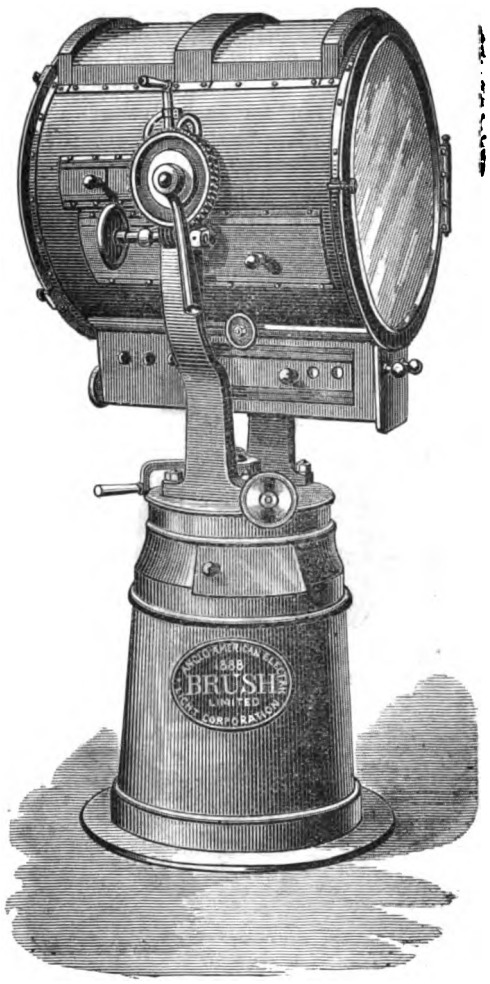
Some side light lanterns for ships having some special features of novelty were also shown at our visit. These consist of an ordinary strong copper ship's lantern, in which the usual oil lamp is replaced by two incandescent lamps. These are mounted on a pivot actuated by a spring; the man in attendance turns this pivot round, bending the spring, and a detent keeps one of the lamps in position,

Digitized by Google

and at the same time lights lamp number one. If any accident happens to this, and the lamp goes out, the breaking of the current releases a spring on an electro-magnet, and relieves the detent; the pivoted arm revolves, and brings lamp number two opposite the reflector, and lights it up. This arrangement is extremely useful where it is absolutely necessary a light should always be shown.

Search Light Projectors.

One of the principal adaptations of the electric light to ship use is that of search lights. The arc light for this purpose is of very much greater candle-power than the ordinary arc lights, which are nominally 2,000 c.p., taking 10 amperes of current. The search light for projectors often take from 75 to 150 amperes of current, giving a light of 30,000 c.p. One of these arc lamp projectors is shown in our illustration for use on board ship. The thick carbons are regulated by a hand feed, and the movement of



Search Light Projector.

the lantern is effected in two ways—by hand, for rough adjustment, in which case the lower handle, which operates a locknut, is loosened, and the whole lantern then moves by hand; and for finer adjustment the lock-nut is tightened, and the worm gearing serves to effect any desired degree of elevation or depression. A feature lately added to these projectors is the flashing arrangement for sending signals. The upper handle shown operates two discs of blackened sheet metal, closes them together with one motion to allow the full beam to pass, and opens them out with the reverse motion to cut off the light; by this means long or short flashes can be used to signal in the Morse code.

These projectors are also much used for navigating difficult passages at night, especially in the Suez Canal, where special apparatus is arranged on the stem of the boats, with a look-out man to discern the way. An illustration of the Suez Canal projector in action is given.

The "Brush" Direct-driving Plant.

This is a combined plant for incandescent lighting for situations where a compact arrangement is required and where a slow speed is available. It is a type of engine designed by Mr. Raworth, a simple and compact form of vertical engine of a thoroughly substantial and practical character, such as any practical engineman could look after. It is largely used for ship lighting, with which the corporation is always more or less occupied. The ship-work is a constant source of occupation even when other work is flagging, many of the fine ocean steamers being entirely fitted with Brush plant.

One of the last plants of this kind recently supplied has run out to Australia and back with total stoppages, day and night, of only 23 hours, which, remembering that these stoppages were when the ship was in port and idle, and not because of any electrical or mechanical difficulty, is probably one of the longest runs made by a dynamo on board ship, and is a regular thing with these ships running to the Antipodes.

The Raworth Friction-Gear Installation.

This plant, which has been favourably noticed in many places, is a combination of low-speed engine with high-speed dynamo, the speed for which is obtained by a balanced friction-gear. A plant of this kind is running at the Brush Corporation's works to supply light for the offices, &c., and the whole plant for 130 lamps is contained in a

Suez Canal Projector.

small apartment not much larger than a cupboard. The over-all measurements of the plant are 7ft. high by 7ft. broad and 4ft. wide. A small Brush engine of the type above mentioned has a large pulley-wheel fixed to its shaft; resting on this is the small pulley of the dynamo, and kept pressed against it by a strong spring. The periphery of the small pulley is covered with a hard layer of paper, and the dynamo itself is hung on trunnions to allow of a slight yield. The advantage of this combination is that the whole plant takes the smallest possible floor space, and retains both the advantage of a high speed for the dynamo and low speed for the engine. It takes, in fact, *less* room than a direct-acting engine and dynamo of the same power, and the engine is enabled to be of a type which is suitable to be placed in the hands of any ordinary workman, who might not be able to deal with the special provisions of an ordinary high-speed direct-driving engine.

A tachometer is attached to indicate the speed of the engine, but the governor acts within a small percentage of normal speed. Two governor belts are fitted in case one breaks, to prevent racing of the engine. There have been over 200 sets of this plant supplied for use on board ship. That now in use at the Brush works has been used for continuous testing of incandescent lamps for 'length of life,' and has run for the last four or five weeks continuously night and day without hitch.

Digitized by Google

Educational Dynamo.

A small type of dynamo, for use in educational establishments, technical colleges, &c., was shown. This has been made for the Heriot-Watt College, Edinburgh. The fields can be connected in any variation—series, shunt, compound, in multiple of two, four, or eight sets, for use in experimenting. One special coil has a special commutator of its own, by means of which the strength of induction in various parts of the field can be experimentally determined, and the strength of the field and other factors can be mapped out. This ought to prove itself very useful in its peculiar department. The machine supplied is used for charging accumulators and driving a motor at the college.

Motors.

Several types of motors were also shown; one of these, a small motor working up to 2 h.p., was shown driving a fan. A special iron-clad motor was also noticed, very strongly made, and shielded for use in mines; this is strung up by an eyelet bolt, and can be drawn up and down the mine shaft, and will stand a great deal of rough usage.

The type of machine intended for the motors for this undertaking will each be capable of working up to 20 h.p. Each locomotive will carry a considerable load of parcels and goods, and, in addition, will draw a heavy passenger car. The system to be used is the overhead line; the station will be situated in the middle of the line, which is not a circle, but a straight out and home line equal to ten straight miles. The current will be taken off in parallel, and the plant will be capable of operating sixteen locomotive and goods cars with attached passenger cars.

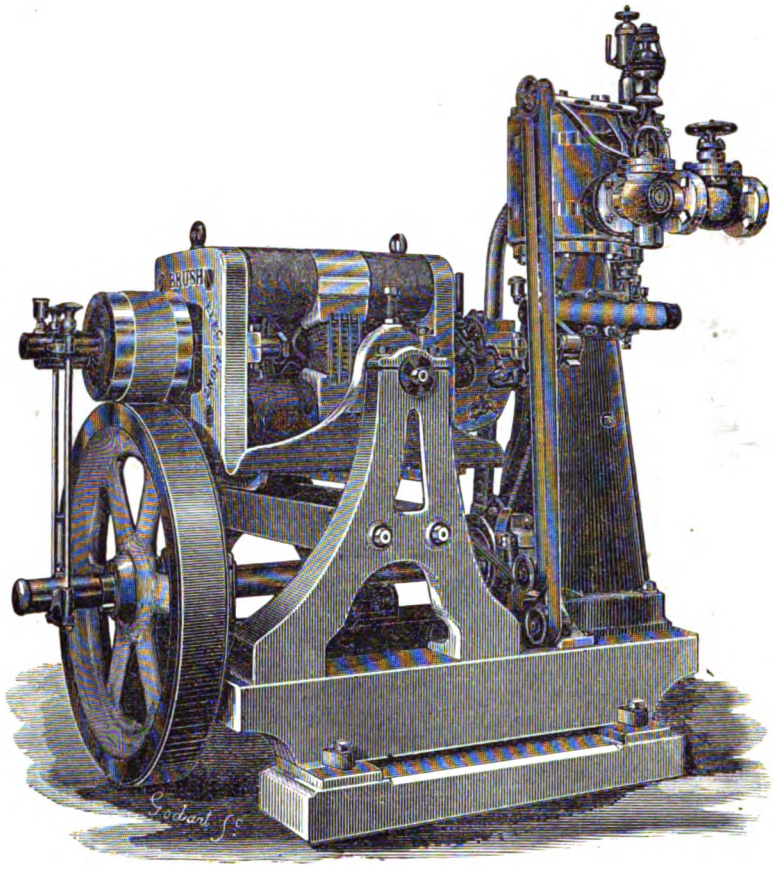
Electro-Deposition and Separation.

The use of dynamo machines for electrical treatment of ores dates from the manufacture of the historical compound-wound Brush plater. The immense "Colossus" Brush dynamos are made for use in the aluminium process taking 400 h.p., and for copper deposition the corporation has supplied a number of low-tension Victoria dynamos.

General Remarks.

We have thus given a comprehensive survey of the work and resources of the Anglo-American Brush Electric Light Corporation, and from what has been said it may be imagined that this enterprising concern, being fairly settled to good work, will be able to deal with its share of the coming lighting schemes. One indication of the way in which the corporation can attack a large influx of work is given when it is mentioned that on receipt of the order for the Melbourne Exhibition for complete plant for 1,000 arc lamps and 3,000 incandescent lamps and all accessories, not any of the necessary plant was in stock, yet the order was accepted and completed for the 40 25-lighter dynamos with lamps and complete plant for the 3,000 16 c.p. incandescent lamps within a period of two months. For the Glasgow Exhibition, likewise, plant for 550 arc lamps was supplied by the Corporation, and a large number for the Barcelona Exhibition, besides the complete arrangement for the illuminated fountain.

Apart from the factory at which they are now working, and which itself is capable of considerable extension, the corporation have a factory in Vienna, and working arrangements with other manufacturers on the Continent. In addition to this, they have other premises in England which can be opened up as soon as the demand for further factory accommodation arises.



Raworth Friction Gear Plant.

Motors giving up to 70 h.p. were also shown; two of these have just been supplied to a foreign Government for use in a factory where water power is available, for driving the factory machinery.

Current Indicator.

A very useful current indicator designed by Mr. Raworth is now in use by the Brush Corporation on their arc circuits. A simple coil wound with wire, to go in series with the circuit, has supported in it a small soft iron piece, which is drawn in, and thus moves the pointer. This is not a solenoid and core, as might appear, but an arrangement by which the iron piece is partly *rotated*, being set originally out of the centre of the coil. It indicates with a long pointer the variation from a normal of 10 amperes.

Electric Railways.

The subject of electric traction has been occupying the attention of the Brush Corporation, and it has recently entered into an arrangement to erect an electric railway of ten miles in length, with a heavy traffic, to be worked at a very high speed. This will be, probably, the longest electrical tramway in Europe, and will be the most important undertaking of its kind this side of the Atlantic.

THE
ELECTRICAL ENGINEER.

Published every Friday.
Price Threepence; Post Free, Threepence Halfpenny.
Editorial and Publishing Offices:
139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months.	12 months.
nited Kingdom.....	3s. 3d. ...	6s. 6d. ...	13s. 0d.
Within the Postal Union	4s. 4d. ...	8s. 8d. ...	17s. 4d.
Other Places.....	4s. 10d. ...	9s. 8d. ...	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, ESQ., *President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of* W. H. WOLLASTON, M.D., F.R.S., *and on April 20th we gave that of* SIR HUMPHRY DAVY, F.R.S., *whose fame as an electrician is still more prominent than that of* WOLLASTON. *Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of* PROF. D. E. HUGHES, F.R.S.

CAUTION.

From his childhood to far into mature age the Englishman is apt to run riot when restrictions are withdrawn. Liberty among plenty at Christmas time leads to illness; indulgence amongst the sweets is very likely to lead to a closer acquaintance with the bitters. The commercial man differs little from the child, while the pure speculator revels in being unrestricted. Readers of hunting literature know how the hunters of America—and for the matter of that in many other places—attract the game. While the hunter himself is hidden, a piece of brightly-coloured bunting flutters in the breeze, and the animal, desirous of knowing more about this strange phenomenon, circles round and round in ever narrowing circles till the fatal spot is passed and a bullet cuts short any further career. The speculator, and in the majority of cases the investor, partakes largely of the nature of the wild animal. The bump of curiosity seems abnormally developed whenever something new is fluttered before them, and if this something new is presented with the high colouring and flavours that promoters know so well how to give, the investor falls an easy prey to the wiles of the money-hunter.

Certain restrictions have been withdrawn from electric lighting, and the charmer is merrily uttering his charm, while we feel it necessary to utter words of caution and to warn intending investors to look carefully into the matter put before them. A buzz of anticipation as to increased work has been heard through the promotion of the Metropolitan Company, with a long list of well-known City men as directors. Now we should like to see such a company succeed, but we fear that this one is not just what is wanted. In the first place, some of the directors have no business on the board of this or any other such company. They have no experience of this class of work, nor is it suited to their idiosyncrasies. Then the company is far too pretentious, and according to its prospectus, if it obtains all the provisional orders it is going to apply for, it will virtually seek a monopoly of the electric lighting of London. So far as its engineering staff or management is concerned, we have no single word of adverse criticism to offer; our animadversions are directed to the finance. Before going further, let us admit with a contemporary that "founders'" shares are a delusion and a snare, even if the promoters have not created them for a worse purpose. At the present moment the capital is half a million, but it is evident that if the promoters carry out anything like their scheme as sketched in the prospectus the future capital will reach five or even ten millions. Now, as we read the prospectus, the *hundred* founders' shares are to receive *half* the profits after 7 per cent. is paid upon the share capital, and to induce subscribers it is pointed out that the

Digitized by Google

capital of the gas companies is reckoned by millions—and we all know their profits are more than 7 per cent. What do these philanthropic directors give for these *hundred* shares, and what do they expect to get for them? They give just the same cash price as for ordinary shares, they get upon the present capital £2,500 for every 1 per cent. after 7 per cent. paid. But evidently this is not the summit of their hopes. They can afford to fight the gas companies tooth and nail, to buy up other minor electric light companies—all at the shareholders' expense—for though they apply for a certain number of ordinary shares, there is no compulsion to hold them, and a few days' Stock Exchange transactions will relieve them of the greater part of such shares, and if only in the sweet by-and-by they can see an 8 or a 10 per cent. on five millions of capital their object would be attained. These founders' shares would then bring in a nice £25,000 a year for each 1 per cent. paid over 7 per cent., and would have as high a value as original New River shares. Is it possible that the red rag held out to investors will induce them to agree to pay on these hundred founders' shares £7,500 when £50,000 is paid to the ordinary shareholders? We assume that a fair price has been paid for what the company has purchased, and therefore the 50 founders' shares reserved for the promoters of the old company are given solely for "being in the swim." It is said that investors will be perfectly satisfied with 7 per cent. for their money, and that they invest with their eyes wide open. No doubt in a measure this is perfectly true, and from this standpoint it may be said that far-sighted individuals are quite at liberty to provide if they can a nice little nest egg for their children. That may be commercial or company morality, and if it is, we have nothing further to say. We venture to think, however, the true action of these founders' shares is not realised, nor is it intended it should be, by the present shareholders. There is no likelihood of even 7 per cent. being paid just yet, and probably never while the capital is only half a million. The holders of these founders' shares do not expect it, but nevertheless they hope for a future gold mine, and this deferred payment is an unknown quantity which may be so utterly out of all proportion to any services rendered, that it should be repudiated at once. There is one conspicuous quality among these directors—viz., that hitherto whatever project they have put their hands to, and kept the management to their own clique, has sooner or later returned the shareholders at least a 5 per cent. dividend. If the clique has thrived during the process, it proves they will know how to manage their own affairs as well as how to satisfy shareholders.

We have said the scheme shadowed out by the prospectus is too pretentious; let us walk before we attempt to run. It is sufficient to prove the commercial practicability of electric lighting in one or two large centres before grasping to supply greater London. Investors must recollect that gas is in the field, and possession is, as we all know, nine-tenths of the law. Gas is not going to give in without a struggle, nor has electricity as yet proved its commercial superiority to entitle it to say with Cæsar, *Veni, vidi, vici.* The data extracted from American successes are altogether fallacious. There electric light has had to compete with gas at a high price, or has been installed when there was no gas. In England, its first successes will be in the wealthier districts, among the club houses and large hotels, in shops, warehouses, and theatres, where gas is deleterious and dangerous, in public buildings where decorations are important; but otherwise outside the main streets, in the houses of the middle classes, the artisans and the poor, in the minor shops, streets, and alleys its time is not yet. It will gradually extend in all directions, and it is this natural extension which may at some future date put the outrageous value upon the founders' shares we have referred to above. Hitherto there has been plenty of work in sight, but the capital at the command of the honest, earnest worker has been scarce. The restrictions that have frightened capital have been removed, and there is still this vast amount of legitimate work without endangering progress by too great attempts at once. Every step taken and every company formed should be such as will bear the strictest scrutiny, otherwise it will be very difficult to obtain the necessary funds to carry out legitimate business. In our criticism we have endeavoured to be bold, plain, and faithful. It would, perhaps, be best for peace to let the world go on in its folly, but it seems to us unjust to permit, without question, any body of promoters to mulct a successful company in the future to an unknown amount for a doubtful benefit in applying for a certain large number of shares as underwriters, which, if they obtain and manipulate sucessfully, may be sold even before allotment, and will, if the markets are satisfactory, be unloaded at the earliest possible moment.

THE CHARGE ON THE ATOM.

BY J. ENRIGHT, B.SC., LOND.

(Continued from page 97.)

The doctrine of the charge on the atom undoubtedly attaches a new difficulty to the theory of "dissociation," for how are we to conceive a number of portions of matter charged with electricity moving through an uninsulated conductor without leakage? No matter how short the periods of freedom may be, some portion of the charge would escape, if not to earth, at all events to the liquid, where it would be rapidly neutralised by similar portions of the opposite kind. But as, according to Helmholtz, there is nothing but the mutual attractions of the charged ions to cause them to recombine, a disengagement of ions should be continually going on. From a solution of cupric sulphate, for instance, solid copper ought to be continually breaking away (when under no electrical influence). If it be urged

Digitized by Google

against this view that the time during which the ions are free is too short to permit the escape of any portion of the ionic charge, it can be answered that the time is also too short to permit the *feeblest electromotive* force to push it with the ion, to which it is supposed to be attached, towards the electrode. But there is the experiment of Prof. Lodge, already referred to, and briefly described. The atom of barium travelled about 60 centimetres in 21 hours through an uninsulated good conductor, and we are asked to believe that its charge made no attempt during all this time either to escape to earth, or to spread itself over the conducting liquid through which it was driven. Such behaviour is very foreign to our experience of electric charges. This experiment alone appears to necessitate a theory of continuous interchange of ions between the molecules of electrolytes when under the influence of an E.M.F.

I suppose it is impossible to compare the tendency to fracture a molecule by the strain of an E.M.F. applied to an electrolyte with the destructive effect supposed to be produced by an encounter between its molecules. Yet one cannot help remembering in this connection that the strain set up in a dielectric by an E.M.F. is often very great—sufficient to fracture glass—and always capable of being detected, while there is little, if any, reason to expect a very destructive effect from the collisions between the molecules of liquids on account of the shortness of the free path. Maxwell can be quoted on this point: "It is true that the molecules, generally, can travel but a very small distance before its path is disturbed by an encounter with some other molecule." But we know that it requires a considerable expenditure of energy to break up a molecule, because the heat of combination of the ions composing it is considerable. And indeed one would expect that the heat of combination of the component ions of the molecules of a substance ought to be closely connected with its conductuity according to the theory under review. Why is it that in some liquids, such as liquefied hydrochloric acid gas, the encounters are not able to cause dissociation; whereas in others, such as a solution of sodic chloride in water, the collisions appear to be very destructive (because it conducts well)—and we ask this question more inquisitively when we remember that the heat of combination of hydrogen and chlorine is only 44,000, while the heat of combination of sodium and chlorine is 195,000, and of hydrogen and oxygen is 79,600? The compounds of carbon and hydrogen are among the worst conducting liquids, although the heat of combination of the elements being comparatively low, one would expect mutual molecular destruction to proceed amain in their liquid compounds.

I have already argued, from the hastening of the precipitation of $SrSO_4$ from a mixture of $SrCl_2$ and H_2SO_4, by passing a current through it, that the strain set up in an electrolyte by that means tends to fracture the molecules directly or indirectly. There is another aspect of this experiment which I consider of great importance. The strain was very likely only one of the forces, the resultant of which effected the dissociation—the last straw, perhaps. But although it was sufficient to disrupt the molecules of $SrCl_2$ and H_2SO_4, it was powerless to prevent the formation of the new molecules—viz., HCl and $SrSO_4$. Now, this is distinctly at variance with the teaching of Helmholtz, for he lays it down clearly that there are no other forces to draw or keep the ions together but the electric forces—the attractions between the electric charges. "If any chemical force existed besides that of the electrical charges which bind all the pairs of opposite ions together, and required any amount of work to be vanquished, an inferior limit to the E.M.F. ought to exist, which forces are able to attract the atoms to the electrodes and to charge these as condensers. No phenomenon indicating such a limit has as yet been discovered, and we must conclude, therefore, that no other force resists the motion of the ions through the interior of the liquid than the mutual attractions of their electric charges." In a word, there is no chemical affinity as commonly understood. In the experiment under consideration, certain molecules are destroyed by the current, and the resulting free charged ions come under its influence. If, as we are taught, there is no chemical affinity, and if, as we are also taught, "the smallest E.M.F. completely dominates charged ions, how then can the molecules of HCl and $SrSO_4$ be formed until the liquid is relieved from the overpowering influence of the current? When the smallest E.M.F. is credited with so much, we are well prepared to expect very firm government from (say) 10 or 12 volts.

In order to test this point, I passed through a mixture of dilute solutions of $SrCl_2$ and $CaSO_4$ the current from the terminals of the conductors which fed a 20 volt glow-lamp. The platinum electrodes were kept about 2½in. apart, and the time was so short before a precipitate appeared, that there was no perceptible rise of temperature. A portion of the same mixture—the counterpart through which the current was not passed—did not show a trace of turbidity for four or five minutes. I infer from this that although the strain of difference of potential may combine with "residual affinities" to break up a molecule, it is powerless against chemical affinity—against that force, whatever we may call it, which caused, under the circumstances stated, the combination of the ions composing $SrSO_4$ and $CaCl_2$. If, as Helmholtz has taught us, the electric forces were the only forces, I submit that on his theory the charged ions when once set free would be hurried off, without being permitted to notice one another, to their respective electrodes by such an E.M.F. as the electrolyte was subjected to in the experiment described. Without comparing the forces brought into play, I consider that it can be safely inferred that a strain capable of breaking up a molecule by acting on the charged ions composing it is also able to prevent such charged ions from combining to form new molecules. And we have the very words (already cited) of Helmholtz to the same effect.

I have endeavoured to regard these experiments from every point of view, and can find no means of escape from the conclusions I have drawn. It did occur to me that the hastening of precipitation may be the effect, not of any strain due to difference of potential, but to some effect of secondary action. I looked as closely as I could into this point. I endeavoured to ascertain at what part of the electrolyte the precipitation took place, and for this purpose passed a current through straight tubes containing $CaSO_4 + SrCl_2$. It was not very easy to make quite sure on this point, on account of the rapidity with which the precipitate scattered and the effervescence due to the disengagement of gas. When the electrodes are pushed far enough apart to get rid of these difficulties, the resistance became so great that the current fell too low for the purpose in hand. I believe the precipitation takes place mainly, if not entirely, near the negative electrode. At all events, precipitation takes place *there* in some mixtures, and to this I will confine myself. It occurred to me even before making the experiment with straight tubes that the nascent hydrogen may react somehow on the salts present to cause precipitation, and I set myself to ascertain whether such was or was not the case. I made a mixture of dilute H_2SO_4 and $SrCl_2$ of such density that precipitation did not take place for about five minutes, and suspended in a portion of it a piece of zinc. Hydrogen was freely disengaged, and after two minutes the zinc was withdrawn, and when the effervescence subsided the state of the beaker in which the experiment was made was compared with a precisely similar beaker containing a portion of the same mixture, but without the zinc. At first I thought that the nascent hydrogen accelerated precipitation, but when purer zinc was used I was obliged, after repeated trials, to decide that such was not the case.

As far as I can see, the experiments I have been canvassing make dead against the "charge on the atom," but I think I can again strengthen my position by falling back upon the experiment of Prof. Lodge, already referred to. A ring of $BaSO_4$ is formed in the connecting tube. According to Helmholtz, the barium is first torn away from the chlorine by the current acting on the positive charge attached to it. It is then carried along by the current, and, since there is no chemical affinity, it cannot combine with the sulphion brought from the opposite electrode. They may pass one another closely, but the overwhelming influence of the current forbids combination—although combination would take place if the current ceased to pass. In a word, according to Hemholtz, Professor Lodge's ring could not be formed. The fact that it has been formed, points to the

Digitized by Google

conclusion already arrived at—viz., that the strain of difference of potential is powerless against chemical affinity, although, as we have seen, under certain conditions it may turn the scale, deciding the fate of the molecule.

And have we not abundant proof of this in ordinary chemical reactions? Oil of turpentine is referred to by Helmholtz as being almost unaffected by the current; but, as is well known, chlorine gas decomposes it, forming HCl. Again, hydrochloric acid gas is decomposed by the metal sodium with formation of NaCl. I do not see how to avoid concluding, from these facts, that hydrogen holds the chlorine more firmly than it holds carbon; and, *à fortiori*, that chlorine holds the sodium with more force than it holds carbon in turpentine—yet a solution of sodic chloride is easily electrolysed. How is such a fact to be explained, except by supposing that the four ions in the solution of sodic chloride in water are in a state of unrest—of unstable equilibrium, and that the strain of E.M.F. turns the scale fracturing the molecule of NaCl?

The easy application of the idea of "the charge on the atom" to the doctrine of valency was undoubtedly the cause of its ready acceptation by chemists. Monads, dyads, &c., were talked of without anything very real underlying such terms, and what appeared to supply the void was eagerly taken up. "He (Helmholtz) tells us, as the results of the application of the modern theory of electricity to Faraday's great experimental law, that the atom of every chemical element is always united with a definite unvarying quantity of electricity. Moreover—and this is most important—that this definite amount of electricity attached to each atom stands in close relation with the combining power of the atom which modern chemistry terms quantivalence." (Speech of Sir H. Roscoe at the close of the Faraday Lecture.)

The creed at first sight looks very inviting, but it is strange that, if such be the real state of things, we ought not to be able, sooner or later, to get a glimpse of these all-pervading charges. There are many reactions, by means of which one would expect to detect them; but before examining such cases it is as well to ask what explanation the theory gives of the ordinary facts of chemistry, such as double decomposition? Potassium iodide and argentic nitrate react silver, iodide being precipitated. Has the theory ever been used to explain such a fact? It is clear that among the four atoms in question there is some "residual affinity" which causes the destruction of the original and the construction of the new molecules. But can anyone picture such "residual affinity" as a residual charge? If we attempt for a moment to figure an excess of positive electricity on the Ag of the $AgNO_3$, and an excess of negative in the iodine of the KI, it will be only for a moment, for the commonest facts rush in upon us, forbidding such a speculation.

Maxwell tried by the touchstone of contact-electricity to account for the atomic charges. "We know that if two metals are brought into contact at any point the rest of their surfaces will be electrified, and if the metals are in the form of two plates, separated by a narrow interval of air, the charge on each plate may become of considerable magnitude. Something like this may be supposed to occur when the two components of an electrolyte are in combination. Each pair of molecules may be supposed to touch at one point, and to have the rest of their surfaces charged with electricity due to the E.M.F. of contact. But to explain the phenomenon we ought to show why the charge thus produced on each molecule is of a fixed amount, and why, when a molecule of chlorine is combined with a molecule of zinc, the molecular charges are the same as when a molecule of chlorine is combined with a molecule of copper, *although* the E.M.F. between chlorine and zinc is much greater than that between chlorine and copper. If the charging of the molecules is the effect of the E.M.F. of contact, why should E.M.F.'s of different intensities produce exactly equal charges?" (*Electricity*, vol. i., p. 349).

It has often occurred to me that this objection might be met. The phenomenon of catalysis has gone hitherto without explanation. It is well known that SO_2 and oxygen do not combine under ordinary conditions, but if both gases be passed over spongy platinum, combination occurs, SO_3 being formed. Now if we assume that the contact of SO_2 with platinum charges it with electricity of one sign, and that contact of the metal with oxygen charges the latter with electricity of the opposite sign, the combination would be explained on the Helmholtz theory. We have, I believe, very good grounds for this speculation, for in the discussion on a paper, by Prof. Lodge, "On the Seat of the E.M.F. in a Voltaic Cell" (*Journal* of the Society of Telegraph-Engineers and Electricians, March, 1885), both sides, as I gather, agree that the contact of a gas with a metal may give rise to electrification. And although the E.M.F. between chlorine and zinc may be very different (as Maxwell says it is) from the E.M.F. between chlorine and copper, yet the opposite charges produces on each of these pairs of substances with a third or a fourth substance, such as water or air, present during the reaction may be equal. In this connection I cannot help referring to the importance Prof. Armstrong attaches to the presence during a reaction of other substances besides those which alone are supposed to take part in it (British Association paper in reply to Prof. Lodge). But when an attempt is made to apply the principle of contact-electricity to cases of displacement and double decomposition such as I have already given, one does not receive much encouragement. It is easy to conceive that the contact of a solution of argentic nitrate with potassic iodide may produce a difference of potential, but then both liquids conduct well and are mixed up, and how, under such circumstances, are we to suppose that mutually attracting charges can remain separate long enough to do any work? But let us ignore this difficulty, and suppose that contact of the molecules of $AgNO_3$ and KI produce charges which remain separate after the manner of the charges on pieces of zinc and copper, which are soldered together. Such charges must be equal and opposite, and according to Helmholtz the charges on the ions composing $AgNO_3$ and KI are also equal and opposite. Where, then, are the forces to cause fracture of the molecules of $AgNO_3$ and KI?

The explanation which I have given—as I conceive—of catalysis on the Helmholtz theory has from time to time appeared to me so suggestive that I have often recurred to it in the hope of explaining common chemical facts by the same mode of reasoning. Chlorine displaces iodine from potassium iodide. Suppose the chlorine becomes charged with the regulation monad quantity of negative electricity when itself or the water containing it in solution comes into contact with the solution of KI. This, according to theory, is no more than what the atom of iodine is postulated to possess, and by virtue of which it is bound to the potassium. Why, then, should the iodine be ousted? Possession is nine points of the law. Again, suppose that chlorine has got, by the contact just alluded to, a greater charge than the monad quantity, then there must be an equal charge of the opposite kind in close proximity to it; and it appears inconceivable that these charges should not, in a conducting liquid, at once combine and neutralise each other, instead of acting on the smaller charges already occupied in holding the atoms of KI together. Moreover, if any electrification of this kind really took place, we ought to be able to detect it by the electrometer. I have made many experiments with this object and refer to *Nature* (Aug. 18th, 1887), where I have described some of them. No electrification could be detected as accompanying or as a result of reactions, *when nothing escaped from the vessel in which they were allowed to go on.* I have found, however, that when gases escape electrification, as a rule, occurs; but as I believe I have proved that such electrifications are independent of the reactions, I shall not discuss them here.

(To be continued.)

ASTONISHED THE LIGHTNING.—A storm broke over the hills at a little place in the West of America, and the lightning took it into its head to strike for a small and lonely hut, where not much harm looked likely to be done. Judging from reports afterwards received, the lightning was considerably astonished to find that over a million pounds of giant blasting powder were stored under that hut.

THE SOLUTION OF THE MUNICIPAL RAPID TRANSIT PROBLEM.*

BY FRANK J. SPRAGUE.

(Continued from page 105.)

The narrow streets, their hilly character, and the lack of paving, especially in the new districts, has made the road one of exceptional difficulty to operate. There are no less than 29 curves, requiring bent rails, the majority being of sharp radius, five being less than 30ft. There are also several sweeps or curves of large radius, several turnouts and cross-overs. The grades are the maximum ever ascended in practice by a self-propelled car depending on track adhesion alone, and many of these grades are very long. Going east there is one section of almost continual ascent for about 5,600ft. with grades varying from three to seven per cent., and going west there is a stretch of 1,900ft. with grades varying from three to ten per cent.

When we first undertook to equip this road in the face of these difficulties, there was the additional discouragement of the ridicule of a great many prominent street railway men and car constructors, as well as electricians. It was only a comparatively short time ago that one of the leading lights in street railway circles made a report to the street railway convention in which he stated that unless some new invention should be made it would be impossible for any self-propelled vehicle to satisfactorily operate under the ordinary condition of street-car service. He, as others, held that the grades and curves met in practice were so severe and the condition of the track so bad that a car propelled by its own wheels could not, under any possibility, day in and day out, be relied upon to move itself. One electrician even made the statement only a short time ago that any man who should attempt to operate on more than a 6 per cent. grade would lose his reputation.

Reliability, economy, simplicity of construction and operation on a scale never before attempted, and under conditions which we could not foresee—this was the problem, and, perhaps, it was well we did not know the difficulties. Then, again, while there have been strong friends of the enterprise in Richmond itself, there was a class that felt anything but pleasure at a stranger's advent.

The change of feeling with which this enterprise has been regarded by this doubting element is somewhat significant. When the franchise was originally secured the city was blest by one car line only, and this had dingy bobtail cars drawn by mules, which, on the heavy grades characterising the topography of Richmond, made very slow time. The new districts were not reached at all. When the present line was proposed there were not wanting philosophers who knew that no road would be operated. Even when the tracks were down these same wiseacres predicted that no cars would ever move over them, and most certainly if they did, the time-honoured mule would be called upon for duty. Even after the cars were put on the line experimentally there existed but little faith that success would be reached. But times have changed. The mules of the competing line are to give way to electricity. The citizens of Richmond are the strongest friends of the electric railroad of to-day, and as regards the street railway community elsewhere, the work which the road has done and is doing and the acceptance of the contract speak for themselves.

The difficulties we have met are many. One of the most annoying at first experienced was that the cars frequently jumped the tracks. A large portion of the track was, as has been stated, laid in macadam and dirt roads, the latter being chiefly in new districts and in a soil of which the chief component was red or yellow clay; and although the curves were of sharp radius, only one guard rail was used, and they were not bound in by paving. The winter months brought frequent and heavy rains. The tracks were found to be settling out of sight in mud, and especially at the curves they were spreading. The cars being large and heavy, with a 4ft. 8½in. gauge, and a 6ft. wheel base, helped to make the curves spread by the tangential pressure of the forward wheels on the outer rails. Mud and stones would get into the grooves, and the cars having a tendency to go ahead instead of being pulled around by the head, as with horses, would climb the track, and, before an inexperienced man could check them, the wheels were down 5in. in the mud alongside the stringer pieces, and the track brakes hard and fast against the tracks. Sometimes it required lifting, sometimes prying, and sometimes a heavy, hard pull on the part of the motors to get them back again. Experience, however, is a great teacher, and among other things which has been taught is this: that money will be saved by a good track construction and the observance of a few practical points All curves should be bound in and paved, and this has since been done in Richmond. They should likewise have two guard rails, because it is much easier to steer a car by its rear wheels by holding them in place than by allowing them to crowd the inner rail and force the forward wheels to climb the outer one. In dry weather, with the large wheel base and sharp curve, it is found advisable to grease the grooved rails.

Another point which has to be carefully taken care of is the character of switch which is put in for sidings and cross-overs. If drop switches are used, they should be of such character as to allow the car to come down easily. Tongue switches are now being put in on all the new work which is being done. It is a rare thing at present to have a car leave the track. I have seen a car in the winter propelled for 100ft. off the track, and also leave and go back on its own account.

The power-house is situated two blocks away from the nearest point of the line, and is almost equidistant from its extremities. As a distributing point, it is, therefore, both theoretically and practically a central station. In the construction no expense has been spared, and the performance of the station has justified it. The battery consists of three cylindrical return tubular boilers of the latest pattern, mounted on a Jarvis patent furnace, their capacity being 125 h.p. each. The water is taken from the city mains or from a well. All feed-water connections are of brass pipe. From the pumps the water passes first through the feed water heater, where it is heated to from 150 to 200degs. Fah. From there it goes to the filter. The draught in the furnace is regulated by an automatic steam damper regulator which, with anything like regular firing, keeps a pressure within two pounds of that for which the regulator is set.

The boilers all feed into one main feed steam-pipe, which in turn leads to a separator, a large iron cylinder into which the steam passes, the water falling to the bottom and the dry steam being carried off at the top. All live steam-pipes in the boiler-room are covered with magnesia.

The present battery occupies less than half the available space in the boiler-room, so that four more boilers can easily be put up when it becomes necessary to enlarge the plant. Two more have just been added. An important feature of these boilers, which are the source of power of the whole system, should not be overlooked, that is, the quality of coal burned. Where a very perfect combustion is obtained a grade of coal can be used which would be impracticable in an ordinary furnace; the mixture at present being used is two parts screenings to one part bituminous, costing from 1dol. 75 cents to 2dols. per tons delivered. As the station is only three hundred feet distant from the depots of three railroads, coal can be obtained almost at the door. From the boiler-room, both the steam and exhaust pipes run in an underground, mineral-wool packed trench to the engine-room.

The railroad engines, of which there are at present three, are of the Armington and Sims' high-speed type, and develop when running at full load 125 h.p. each at 250 revolutions.

Each engine drives two special Edison dynamos of 40,000 watts capacity each, wound for 500 volts maximum pressure. The dynamos feed into copper "bus" bars supported on the walls by porcelain insulators.

Each machine has its independent ampere-meter, and in addition there is a general ampere-meter at the end of the positive "bus" bar. From this bar the current passes to four snap switches, each switch being connected through a three-plug safety switch block to one of the feeders supply-

* Read before the American Institute of Electrical Engineers, June 19th, 1888

Digitized by Google

ing current to the main line wire. These four feeder wires tap into the line wire at different points, thus maintaining the pressure approximately equal all along the line. At the ends of one of the feeders in the central station pressure indicators are to be attached, which will indicate the voltage at the junction of one of these feeders with the main current wire, and this will serve as a guide.

The electric circuit consists of two parts—the overhead and the ground circuit, each being of compound character. Along the kerbstones at distances of 125ft. are 30ft. poles, inserted into the ground a distance of 5ft. Great difficulty was experienced at first on account of the clayey character of the soil, and it became necessary at the corners to put in very heavy poles, which were embedded in concrete and stones to prevent settling out of place after heavy rains. These poles carry the main circuit which extends throughout the entire length of the road, and is a copper wire three-sixteenths of an inch in diameter; this is called the main conductor, for on it depends the operation of the road in case of accidents or repairs to the contact wire.

The arrangement of main and working conductor are as already set forth.

This main conductor is, as stated, supplied at widely-separated points by feeders, which come from the main supply at the central station. Without the use of these feeders, which can also be reinforced if necessary, the size and cost of the overhead conductors would be very largely increased. The curves are formed of a series of short chords, which approximate the central line of curvature.

The current is taken from this working conductor by a light structure on top of the car. This consists of a low skeleton framework which carries an adjustable swivelling trunnion, having at its upper end a jaw in which is suspended a counter-balanced trolley-pole, having at its extension a grooved wheel held by a spring against, and making running flexible contact with, the under side of the working conductor. The flexibility of this arrangement is very great, it being able to follow with perfect facility variations of the trolley wire two or three feet in either horizontal or vertical direction, at any speed, and around any curve. What is all important, it relieves the line of strain instead of adding to it. When getting at the end of the track, this trolley trunnion is swung around so as trend in a proper direction abaft the centre of the car. If off the line, it can be replaced from the car quickly and easily in the darkest night. From the trolley the current passes through a protected wire to the lightning arrester, and thence to two switches, one at each end of the car, whence, after whatever commutation is necessary, it goes to the motor circuits, and thence to the wheel frame.

The return circuit is through the track, and thence by both metallic and ground circuits to the station. Each section of rail is joined to a copper ground wire, which runs throughout the length of the road underneath or alongside the stringer pieces, which is done to prevent appreciable differences of potential existing between the rails. As a further precaution, at intervals of 500ft. this ground wire is connected to an earth plate, and at seven points widely distributed. These ground plates are supplemented by heavy iron pipes sunk into iron ore, or 12in. water wells, about 25ft. deep. The ground wire is connected to the station, and there is also a main ground connection made there in a 30ft. well through a large zinc plate, and another to the entire water works system. Some modifications of the overhead system are now being made which will make it impossible for any accident to one section of the line to disable the remainder; will enable the different sections to be operated independently; and, in case of a fire which may necessitate the blocking or temporary disabling of one part of the line, will allow this section of the line to be cut out of action either automatically or at will.

Each car is fitted with a duplicate and very powerful motor equipment. This is carried entirely beneath the car body, is very compact, out of sight, and necessitates no radical change in the construction of the car. The body had to be stiffened a little and 3in. steel axles put in. One of the great objections which have been met with in applying motors, whether steam, electrical, or of any other character, to the propulsion of street railways, has been the difficulty of getting sufficient track adhesion to operate the car under all conditions of track, loads, and grades. Especially was this objection true in Richmond, where it was manifest that no application of a motor system could be fully successful unless the entire weight of the car and its contents was made available for traction.

One of the manifest reasons is, of course, the slippery character of the track under many conditions. Another thing should also be noted, and that is that it is almost impossible in practice to cast all wheels of exactly the same circumference, or at least so that the paths described by the lines of contact shall be the same. Moreover, on curves the wheels are all travelling over paths of different lengths. Theoretically, the wheels should be independently driven, but since this is not possible, it follows that the next best thing is to drive each pair of wheels independently. It is a fact which admits of no dispute that there are conditions of track which will not permit of a car being driven from one pair of wheels only, and this difficulty is often augmented by the fact that if one pair of wheels only is used they will sometimes be leading, sometimes following; on heavy grades, with one platform reserved for the driver, there is a very serious displacement of the centre of gravity, and there may be very much more weight upon one pair of wheels than on the other. The whole experience in Richmond has been to emphasise the value and necessity of independently driven axles.

To accomplish this, one motor is centred upon each axle, and to allow the required freedom of motion, and at the same time to preserve perfect parallelism in the meshing of the gears, and also for taking part of the weight of the motor off the body of the axle and to throw it on to the journals, one end of the motor is supported by double compression springs playing upon a loosely suspended bolt, which is supported from a cross girder in the bottom of the car.

The motors are, then, so to speak, weighed or flexibly supported from the car body, and the motion of the armatures is transmitted to the axles through intermediate gearing, of compact form and great strength, so that whenever the axles are in motion, there is a spring touch of the pinions upon the gears. Barring friction, a single pound pressure exerted in either direction would lift or depress the motor a slight amount, and no matter how sudden the strain, whether because of a variation of load or speed, or a reversal of direction of rotation, it is impossible to strip the gears unless the steady strain exceeds the strength of the iron, the pressure on the gears always being a progressive one. The motor armature makes nearly twelve revolutions to each revolution of the car axle.

The motors, although in one sense independent, are connected with duplicate switches at either end of the car, which afford simultaneous control of both machines. These motors, which are of normal capacity of 7½ h.p. each, can for a short time work up to 30 h.p., and are capable of producing a tractive effort of over 3,000 lbs. at 50 per cent. efficiency.

The machines are controlled by a single movement switch, which effects the various commutations and reversals. They run with fixed brushes in both directions, and under all loads. They are run without any covering, and I have no doubt of having street car motors in such condition soon that the cars will be run over a pit, and the machines washed down with a hose.

The cars can be run at widely different speeds, varying from the slowest crawl to twelve or more miles per hour. They can be started and stopped without the use of brakes in the space of three or four inches, and when making the normal running speed can, in an emergency, be stopped and reversed without brakes within less than a quarter of a car length. The starting, although prompt, is easy, and without shock or jar.

Emergencies sometimes bring out qualities of motors which are unexpected, or which, at least, if counted on are rarely ever brought into play. On one occasion a man was decending a 6 per cent. grade with a heavy load when his brake chain parted. Seeing a sharp curve right ahead of him, which he knew he would leave if he struck it at the speed he was running, he instantly reversed his machines and brought his car to a standstill, and on the rest of his

Digitized by Google

trip handled his machines entirely with the motors. On another occasion a man, passing from behind one car directly in front of another, was struck and knocked down by the dash-board. Although the car was moving at a lively gait, the machines were reversed and the wheels stopped within a foot of the man. By any other method

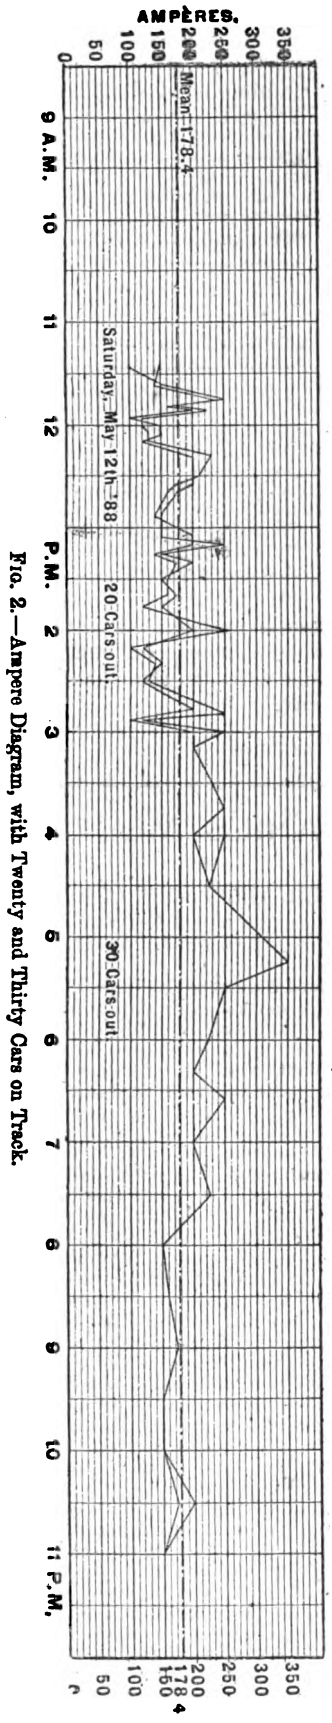

Fig. 2.—Ampere Diagram, with Twenty and Thirty Cars on Track.

of propulsion he would have been killed. Frequently on a 10 per cent. grade, with a loaded car, the brakes have been thrown off, the machines reversed, the car stopped and started backward up hill within less than one-half of its length, a test of the most remarkable severity.

In noting the control of the car, one is struck at the remarkable character of the traction, and cannot help wondering where it comes from; unquestionably it is in a large measure due to the fact that every pound of weight is available for traction, and that the two axles, being independently driven, can take their own speed, and each pair get the best grip.

Another thing to be noted, where the ground circuit is

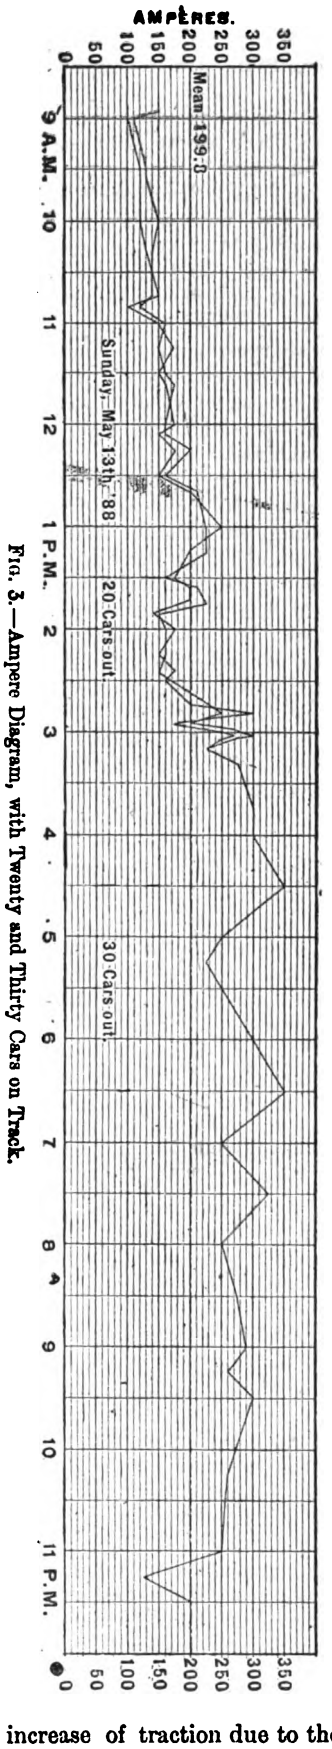

Fig. 3.—Ampere Diagram, with Twenty and Thirty Cars on Track.

used, is the increase of traction due to the passage of the current from the wheels into the rails. Exactly what molecular action takes place has not been ascertained. It may be simply heating at the contact surface; but the fact remains that the traction is very largely increased. The magnetic condition of the wheels and tracks also has some function in this increase of traction. The wheels and axles

Digitized by Google

are magnetised by the method of motor construction and mounting, and also by the passage of the current through them. The tracks are likewise magnetised by the current passing through them, and also by the rolling contact of the wheels. Yet, admitting all these aids, the results have been extraordinary.

Sixteen-foot closed cars carrying picked loads of fifty-five to sixty passengers, and having a total weight of 15,000 lbs., are operated on the 10 per cent. grade, often with a slippery and slimy rail, and on 27ft. curves, without the use of sand or extra help.

These same grades and curves have been ascended without sand after one of the worst sleet storms which has visited this section for years. Various tests under the most unfavourable conditions have been made, cars often being required to cut their way through clay, snow, and ice when the tracks were out of sight. No severer test could have been made, and the power and tractive effort developed have exceeded the most sanguine expectations.

Cars have often been stopped and started on the heaviest grades, and in the sharpest curves. One motor has propelled two cars around sharp curves and up six per cent. grades. One car has pushed another of greater weight around the sharpest curves and up seven and eight per cent. grades both straight and combined.

I have no hesitation in saying that with a clean track, and with proper gearing, these cars could mount a 15 per cent. grade, depending on adhesion alone. During the four months' operation, although there have been troubles and changes have been made while the cars were running commercially, no car has been pulled a foot by animal power; if any accident has occurred to a motor the car has gone along with one machine, oftentimes with heavy loads and on heavy grades, or in some cases has gone home in company with another car. One hundred and forty men who did not know the difference between a motor and a hand saw have been broken in to handling these cars, oftentimes with remarkably short training. Up to Saturday, May 4, the number of regular cars on duty had not exceeded twenty. On that day at 4 p.m., the hour when traffic becomes exceptionally heavy, we began putting out ten open cars, starting them from the eastern car house alternating with the closed cars, but finally banking them all up at the Old Reservoir. At 6 p.m. they were started home, and shortly afterwards these 10 open cars, headed by a closed car, were all run at full speed close together down the east-bound track of Clay-street. At one time 14 cars were on the line between Clay and Hancock streets and the Old Reservoir, and shortly before 7 o'clock there were about 22 cars on the line between Capitol-square and the Old Reservoir, and at 7 o'clock 30 cars were on the line, the closed cars being very heavily loaded, many of the cars being run with two minute intervals. The three boilers, whose capacity is 375 h.p., were then supplying three Armington and Sims' engines of 125 h.p. capacity, which were driving the six railroad dynamos, and two Westinghouse engines of 110 h.p. capacity, which were driving two alternating current dynamos and exciters, with an equivalent load of 1,060 incandescent lamps. The mixture was enriched and the firing of boilers became pretty active, there being, in addition to the 30 cars badly banked, about 110 h.p. taken for lighting.

The highest reading, however, on the line was less than three-quarters of the normal capacity of the dynamos, which were originally intended only for 30 cars, and the average reading for this number was only a trifle over half the normal capacity.

The ampere readings taken at intervals of ten and fifteen minutes give a load diagram which is really higher than a continuously recording instrument would show. Figs. 2 and 3 show the ampere readings with twenty and thirty cars.

The figures which follow, being based upon an actual service increasing from eight to thirty cars, and extending over a period of four months under the most trying circumstances, and at the most critical and care-requiring period of the enterprise's existence, will give street railway men the most careful and liberal estimate of every possible expense attending the operation of the road which is in any way dependent upon its electrical features. The operating expenses are given under two heads; first, the central station operating expenses, and second, the road operating expenses, the two constituting the total cost of motive power. These are given in detail, and they will probably be found to cover every expense, although in some small ways the distribution of these expenses may be found to be changed by several months' longer running. The fuel and other incidental expenses of the station are from the engineer's record, and checked by the readings of the electrical instruments.

For thirty cars running on a double track the central station expenses are about as follows:

52 42-100 cwt. coal at 10 cents	$5.84	
113 70-100 cwt. screenings at 7 cents	7.96	
5 pints cylinder oil, at 75 cents per gallon	.47	
5 pints dynamo oil, at 30 cents per gallon	.18	
3 pounds waste, at 10 cents	.30	
Water at current rates	3.00	
Fuel, &c.		$17.75
1 day engineer	$3.00	
1 night engineer	2.25	
4 firemen	6.00	
1 cleaner	1.50	
2 dynamo men	3.50	
1 electrician	4.00	
Labour		$20.25
Lighting		.50
Depreciation and repairs on dynamos, 3 per cent.		1.50
Depreciation and repairs on engine and boilers, 10 per cent.		4.38
Total central station expenses		$44.38

Or $1.48 per car making eighty miles.

[The central station being operated for twenty-four hours for lighting and power purposes, the lighting company has now assumed charge, and rents the power to the cars at 1 dol. 60 cents per day.]

(To be continued.)

COMPANIES' MEETINGS.

NATIONAL TELEPHONE COMPANY.

The eighth annual meeting of the National Telephone Company took place on Saturday at the offices of the Company, 162a, Queen Victoria-street, E.C.

Colonel R. Raynsford Jackson (Chairman of the Company) presided, and said: Gentlemen, the report contains within itself all that is necessary for you to know of the affairs of the Company. You will see that the gross revenue reached on June 30 last was £109,572. 12s. 7d., and that the increase for the year was £17,235. 10s. 3d. I will ask your attention to the abstract of accounts; there you will see that the first three columns are headed differently to the heading used in former abstracts. The heading in those was "gross revenue"; that was to a certain extent misleading, because some people thought it meant the gross revenue entered in the accounts for the year, whereas it is the revenue reached by June 30; and it is divided in the present abstract into two headings—annual rentals and sundries, and fee messages. You will see that the fee message revenue is steadily growing, and I thought it would be interesting to you to watch the development of this source of profit. The trunk pole lines are now 842 miles, an increase of 199 miles since last year; and the wire they carry is now 2,509 miles, an increase of 590 since last year. There is also an increase of 26 in the number of exchanges, and of 1,470 in the number of lines, the present number of lines being 9,324. I now call your attention to the list of our centres on the second page. You will see the large number of towns that are grouped together and have communication with each other through the instrumentality of the trunk system. By next year we shall have a considerable increase in the number of towns so connected, and by the middle of September Sheffield and Birmingham will be in telephonic connection, which will combine the Midland district with Nottingham and carry a trunk line from Birmingham through the Potteries to the frontier of the Lancashire and Cheshire Company's system, and they will meet us there. We shall then have trunk communication in almost a straight line from Birmingham to Manchester and the whole Lancashire system. This will give us the advantage, when London and Birmingham are telephonically connected, of a short connection between Manchester and London. London also will be connected with Nottingham and Yorkshire through Birmingham. I now call your attention to one feature in the capital account, that is that £70,700 out of £75,000 debenture bonds have been converted into debenture stock. £60,900 of the debenture bonds were at 6 per cent. interest and £14,100 at 5 per cent. The debenture stock has been issued at 4½ per cent., thus greatly diminishing the interest account. I wish now to call your attention to the position we occupied before Nov. 29, 1884, and if you will look at the map you will see the boundary of our districts marked in red. You will see in red several small spots. These represent telephonic oases in a huge barren district, for they were the only areas in which

Digitized by Google

we were allowed to exploit the telephone. We were not allowed to connect town and town; and had the system then in vogue continued, it would have been utterly impossible to make the progress which I have described to-day, and to cover the country with exchanges and trunk wires. Mr. Fawcett, a liberal and large-minded statesman, presided over the Post Office, and he, in the interest of the public, gave us new licenses, enabling the lines in all directions to connect town and town, and rendered possible the development at which we have arrived to-day. Had it not been for this, the position of the telephone in this country, which leads the van in enterprise, would have been absolutely disgraceful. With reference to amalgamation, I have only to confirm the words used by Mr. Brand when addressing his shareholders. He mentions as one of the difficulties in the way of amalgamation the difference of opinion that may arise as to the valuation of the prospects of future development. I do not think that when fair-minded men approach each other with a view to obtaining a given result difficulties are allowed permanently to stand in the way—the means are generally found to overcome them; but I will say this much, as regards the National Telephone Company, that we shall have to be specially guarded against giving capital for prospective improvement in other companies, the dividends upon which may have to be paid out of the solid earnings of the National Telephone Company. I do apprehend, however, that the necessity of taking care of ourselves upon this point will stand in the way or be an important factor in our negotiations. It may not be unimportant, when we are so much in contact with a great public department as we are with the Post Office, that it should be known to our shareholders that our relations with that department continue to be of the same friendly character as hitherto. The Chairman concluded by moving the adoption of the report.

Colonel Harrison seconded the motion, and it was carried unanimously.

On the motion of the **Chairman**, the meeting approved a dividend upon the ordinary capital for the second half of the year at the rate of 5 per cent. per annum, allowing for £2,500 to be placed to the reserve fund, and £3,253. 5s. 1d. to be carried forward.

The **Chairman** moved the re-election of Mr. John Bruce, of Edinburgh, as a director, and the motion was seconded by Mr. Sands, and carried unanimously.

On the motion of the **Chairman**, seconded by **Colonel Williams**, the re-election of Mr. Jeremiah Garnet, of Manchester, to the Board was similarly carried.

A vote of thanks to the Chairman, Directors, and Secretary, moved by Mr. Dixon, concluded the meeting.

NEW COMPANIES REGISTERED.

Monte Video Telephone Company.—The English Bank of the River Plate invite subscriptions for £180,000 of share capital, divided in 24,000 six per cent. preference and 12,000 ordinary shares of £5 each, of the Monte Video Telephone Company, Limited, which has been formed to acquire as a going concern the concession, rights, patent privileges, plant, exchanges, and other property belonging to the telephone company known as La Sociedad Anonima Compania Telefonica La Uruguaya, in the city of Monte Video. The Uruguay Company was incorporated in the month of April, 1885. It commenced operations with about 450 subscribers, since which it has made rapid progress, and by the latest information received from Monte Video, the total number of telephones now working are 1,610. A telegram from Monte Video states that the net receipts for the first four months of the Uruguay Company's current year ending 30th June last were 18,800dols., or at the rate of 56,400dols. per annum, equivalent to £12,000. The Directors of this Company are:

Arthur Holland, Esq., 2, East India-avenue, E.C., director of North-Western of Uruguay Railway Company, Limited.

Thomas D. Peters, Esq., late of Messrs. Peters and Hall, Buenos Ayres.

Edward F. Powers, Esq., late managing director of the River Plate Telephone and Electric Light Company, Limited, who will join the Board after allotment.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The traffic receipts of the Brazilian Submarine Telegraph Company for the past week amounted to £5,601.

Direct United States Cable Company.—The Direct United States Cable Company, Limited, state that their main cable between Ireland and Halifax (Nova Scotia) is now in efficient working order.

Eastern Telegraph Company.—The Eastern Telegraph Company's traffic receipts for the month of July, 1888, amounted to £48,735, and to £45,805 in the corresponding period of 1887.

Eastern Extension, Australasia, and China Telegraph Company, Limited.—The traffic receipts of the Eastern Extension, Australasia, and China Telegraph Company, Limited, for the month of July, 1888, amounted to £35,233, and to £38,520 in the corresponding period of 1887.

Commercial Cable Company.—A circular has been distributed by this Company to the effect that on and after the 1st September, 1888, and until further notice, the charge for the transmission of telegrams, "via Commercial," between Great Britain and Ireland and the city of New York, Brooklyn, and New England States, the provinces of Quebec and Ontario, Newfoundland, St. Pierre, Prince Edward Island, Nova Scotia, and New Brunswick will be 1s. per word.

Maxim-Weston Electric Company.—Mr. Hugh Watt, M.P., has resigned his position of director and managing-director of the Maxim-Weston Electric Company, Limited. The engagement of Mr. J. Wright as secretary has been terminated by the Board, and Mr. Samuel J. Boyce (of the firm of Messrs. Boyce and Ramsay, chartered accountants) has been appointed secretary. The offices of the Company have been removed to No. 2, Metal Exchange-buildings, 95-97, Gracechurch-street, E.C.

Companies of the Month.—The following companies have been registered during the past month:—

Crompton and Co., £5 shares	£140,000
City of Westminster Electrical Syndicate, £1 shares	10,000
East Strand and District Electric and Power Company, £5 shares	5,000
Monte Video Telephone Company, £5 shares	180,000
Submarine Mining and Torpedo Explosives Company, £1 shares	30,000
Woodite Company, £10 shares	50,000

PROVISIONAL PATENTS, 1888.

JULY 27.

10,875. **An improved surgical apparatus for electro massage.** William George Johnson, 9 and 10, Southampton-buildings, Holborn.

10,887. **Improvements in electric cartridges and primers.** Selden Allen Day, 169, Fleet-street, London. [Date applied for under Section 103 of the Patents, &c., Act, 1883, 23rd March, 1888.]

10,890. **Improvements in motors.** William Wynne, 142, Fleet-street, London. (Joseph Beduwé, Belgium.)

10,900. **An improved electric alarm for varying levels and pressures.** Andrew Siegmann, Gray's Inn Chambers, 20, High Holborn, London, W.C.

JULY 28.

10,904. **Improvements in electric batteries.** R. Sauerwald, 45, Southampton-buildings, London.

10,929. **Improvements in magneto-electric generators and appliances for use in connection therewith.** Edward Cox-Walker and Alan Archibald Campbell Swinton, 75, Queen Victoria-street, London, E.C.

10,941. **Improvements in the arrangements for the lighting of railway trains by electricity.** Illius Augustus Timmis, 2, Great George-street, Westminster, S.W.

10,945. **An improved cut-out for electric circuits.** William Hopkin Akester and George Hopkins, 57, Chancery-lane, London.

10,952. **Improvements in dynamo-electric machines.** Lazarus Simon Magnus Pyke and Harry Theodore Barnett, 433, Strand, London, W.C.

10,954. **Improvements in or connected with dynamo-electric machines.** Ernest Heinrich Geist, 433, Strand, London. (Complete specification.)

10,956. **An electrical lighting apparatus for medical and surgical purposes.** Castle Smith, 54, Fleet-street, London. (R. Blaensdorf, Nachfolger, Frankfort-on-Maine.)

JULY 30.

10,980. **Improvements in internal combustion thermo-motors.** James Hargreaves, 4, Clayton-square, Liverpool.

10,982. **Improvements in electric battery cells and combinations of same for electric lighting, power, signalling purposes, firing torpedoes, &c.** Thomas Pease, 32, Holborn hill, Higher Tranmere, Birkenhead.

11,019. **Improvements in electric bells.** Walker Moseley, 82, Montpelier-road, Peckham.

11,020. **Improvements in the method of producing aluminium chloride.** Camille Alphonse Faure, 24, Southampton-buildings, Chancery-lane, London, W.C. [Date applied for under Section 103 of the Patents, &c., Act, 1883, 6th March, 1888.]

JULY 31.

11,050. **The cure of toothache by voltaic couple.** Joseph Parkinson, Samuel Fawcett, and Charles Frederick Parkinson, 30, South Regent-street, Lancaster.

11,065. **Improvements in or relating to apparatus for regulating the brilliancy at which lamps included in the secondary circuits of induction coils or electric converters may be caused to burn.** William Phillips Thompson, 6, Lord-street, Liverpool. (George Westinghouse, jun., United States.) (Complete specification.)

11,082. **An improved mode of an apparatus for transmitting electrically autographic messages, signs, and markings.** Philip Arthur Newton, 6, Bream's-buildings, Chancery-lane, Middlesex. (Elisha Gray, United States.) (Complete specification.)

11,100. **Improvements in permanent way for vehicles propelled by electricity.** Joseph Kincaird, 47, Lincoln's-inn-fields, London.

11,106. **Improvements in electrical signalling apparatus.** Henry Harris Lake, 45, Southampton-buildings, London. (Edward Davis and Ebenezer Baker Welch, United States.)

11,108. **Improvements in electric conductors or cables, and in means for preventing disruptive discharges therefrom.** Philip Middleton Justice, 55 and 56, Chancery-lane, Middlesex. (Edward G. Acheson, United States.) (Complete specification.)

Digitized by Google

AUGUST 1.

11,147. **Improvements in the means or apparatus for transmitting and receiving, and for recording and reproducing speech or sounds.** Leon Le Pontois, 169, Fleet-street, London.

AUGUST 2.

11,174. **Improvements in and connected with the method of and apparatus for electrically lighting railway trains.** Thomas Parker, of the firm of Elwell-Parker (Limited), 70, Market-street, Manchester.

11,182. **Motive power for driving electric and other machinery.** Francis Stradwick Harwood, Leicester House, Cromer, Norfolk, and Henry George Cheesman, Winterton, Doncaster, Lincolnshire.

11,184. **Improvements relating to electric arc lamps.** Francis Teague and Frederick Ernest Teague, Crown-yard, Stanhope-street, N.W.

COMPLETE SPECIFICATIONS ACCEPTED.

AUGUST 2, 1887.

10,663. **Improvements in or relating to electrical type-writers and printing telegraphs.** Alfred Julius Boult, 323, High Holborn, Middlesex. (James F. McLaughlin, United States.)

AUGUST 5, 1887.

10,785. **Improvements in clocks and apparatus for winding the same by electricity.** James Grieve Lorrain, Norfolk House, Norfolk-street, London, W.C.

AUGUST 6, 1887.

10,836. **Improvements in electrical firing mechanism for ordnance.** Charles Ambrose McEvoy, London, Ordnance Works, Bear-lane, Southwark, Surrey.

SEPTEMBER 2, 1887.

11,928. **Improvements in apparatus for indicating the presence of fire-damp in coal mines or other places.** Joseph Wilson Swan, 47, Lincoln's-inn-fields, London.

SEPTEMBER 22, 1887.

12,880. **Improved method of producing solid metal sheets by electro-deposition suitable for compass cards, stencils, and open worked flat or curved articles for decorative and other uses.** Wallace John Reynolds, 166, Fleet-street, London.

OCTOBER 10, 1887.

13,709. **Indiarubber compensators for telegraph signal and other wires.** Robert Sebastian Bozon, 144, Kennington-road, Lambeth, London, S.E.

MARCH 27, 1888.

4659. **Improvements in apparatus for making and breaking electrical circuits in connection with call or alarm boxes, and recording the same automatically on dials.** Fredk. Thomas Schmidt, Sunbridge Chambers, Bradford, Yorkshire.

MAY 29, 1888.

7848. **Improvements in or relating to indicators for alternating electric currents.** William Phillips Thompson, 6, Lord-street, Liverpool. (George Westinghouse, jun., United States.)

7849. **Improvements in or relating to apparatus for detecting and locating faults in alternate current electric circuits.** William Phillips Thompson, 6, Lord-street, Liverpool. (George Westinghouse, jun., United States.)

MAY 31, 1888.

7998. **Improvements in and relating to shades and reflectors for incandescent electric lamps.** Frank Holman, 45, Southampton-buildings, London.

JUNE 23, 1888.

9206. **Improvements in galvanic elements or batteries.** Carl Lütcke and Paul George, 166, Fleet-street, London.

JUNE 26, 1888.

9331. **Improvements in relays.** Frederick Stitzel and Charles Weinedel, 18, Buckingham-street, Strand, London, Middlesex.

JULY 3, 1888.

9660. **Improvements in electric motors and dynamo machines.** Alfred Julius Boult, 323, High Holborn, Middlesex. (Orazie Lugo, United States.)

9661. **Improvements in telephone transmitters.** Alfred Julius Boult, 323, High Holborn, Middlesex. (Julius Emner, jun., United States.)

SPECIFICATIONS PUBLISHED.

1887.

4533. **Electric locomotives and vehicles.** M. R. Ward. 8d.
9235. **Miners' safety lamps.** J. Treherne. 8d.

NOTES.

Brussels.—The electric light is to be installed at the Midi Station, Brussels.

Overhead v. Conduit.—The cost of the best overhead line for an electric railway, on engineering authority, is about one-tenth the cost of a conduit system.

Personal.—Mr. Henry Cunynghame, the well-known author of the work on the Electric Lighting Act of 1882, has been appointed to the secretaryship of the Parnell Commission.

Electric Bridge Railway.—The Thomson-Houston Company are going to construct an electric road over the Missouri River, to connect Omaha with the other side over a special bridge.

Calcutta.—We understand that the Calcutta agent of one of the English firms has secured the contract for lighting the United Service and Bengal Clubs with electric light at an early date.

Sea-Bathing by Arc Light.—A tall arc light has been erected about thirty feet out from the shore at Crescent Beach, near Boston, U.S., so that the bathers can disport themselves at night under the arc's mild beam.

Malvern.—Application has been made to the Local Board for leave to put overhead telephone wires at Malvern. Any electrical work there will have to be underground, however, for the Board will not allow any overhead wires in their picturesque watering place.

Lincrusta Pushes.—Pushes for electric bells made with covers of Lincrusta-Walton washable wall-paper, to match the decoration of the room, are the latest thing in this line. They are introduced by Messrs. Woodhouse and Rawson, and are made in various colours and patterns.

A Large Installation.—Kansas is busy preparing for a large central station for distributing steam of 3,500 h.p., four electric light stations with a total capacity of 10,000 incandescent and 1,000 arc lights, with the piping and wiring of the entire city to distribute light, heat and power.

The Tesla Motor.—The patents of Mr. Nikola Tesla, whose invention of the alternate current motor were recently described by us, have been purchased by the Westinghouse Company. The manufacturing preliminaries are being pushed forward, and the Tesla motors will soon be in the market.

Canada.—The Edison patents having been more or less upset in England and the United States, efforts are being made to annul the patent for Canada. The plea is non-compliance with the Patent Act, and the Westinghouse, the United States, and the Consolidated Electric Light Companies are contesting the Edison patents.

A Bureau of Electrical Testing.—The Johns Hopkins University will establish an authorised department for the comparison and standardising of electrical instruments for America. The work will be directed by Dr. Henry A. Rowland, and the comparisons will be made by Dr. G. A. Liebig, who has been appointed assistant in electricity.

Without Conductors.—The Ansonia railway is run on the Thomson-Houston system, which, it is well known, is not a storage method. It was therefore surprising at first to read that the line "is a complete success in every respect, and was the first to run electric cars without conductors." On reflection it is evident that it is "not that sort" of conductor they do without.

Second-hand Plant.—It has been suggested that a list corrected and issued weekly of new and second-hand plant, to be disposed of or hired on favourable terms, would be advantageous to the industry. We have made arrangements to carry out this suggestion, and this week give a specimen list of such plant. As far as possible, samples of the goods to be sold will be found at the office.

Carriage Traction.—It will be remembered that a short time ago M. Volk, of Brighton, fitted up a carriage with accumulators, and ran the carriage over considerable distances by the aid of electricity. The description of this experiment caused the powers that be at Constantinople to desire a similar carriage, and we understand one was ordered, which is being fitted up by Messrs. Immisch.

Lightning in a Post Office.—During one of the late thunderstorms a telegraph instrument at the Brigg railway station was struck and damaged, and much alarm was caused at the post office at the same place by a loud report proceeding from a telegraph instrument. The office immediately afterwards filled with smoke, but fortunately nothing took fire and no personal injury was sustained.

Bank of England.—The electric light seems to be appreciated at the Bank of England. After a careful trial of electricity, the authorities have found the advantages of the light so evident, that they continue to extend the system. Messrs. Drake and Gorham have just completed an installation for the supply of 500 lights, and have now received instructions to put down two additional engines for lighting another set of offices.

Accumulators at Sea.—The English Admiralty are beginning to recognise the advantages of accumulators for ship-lighting, a fact which has long been evident to many foreign powers. As a result Messrs. Drake and Gorham have recently received instructions to fit batteries to both the Royal yachts, and they are now supplying a similar set of their special ship-lighting cells for the "Britannia" and the "Hindostan."

Chicago Underground Railway.—Chicago is trying to get an underground railway on the model of London, but run and lighted by electricity, with a circuit of twenty-seven miles. Elevators will be used to bring the people to the street level. A company has been formed with a capital of 27 million dollars. The plan is feasible enough in the present state of engineering; but the question is, will it pay on the large outlay?

Ratios of Electric Conductivity.—F. Kohlrausch has given in *Wiedemann's Annalen*, No. 4, the electric conductivity of hard steel as 3·3, soft steel at 5·5, and wrought iron as 7·6, mercury being 1; while their thermal conductivities in C.G.S. units were: Hard steel, 0·062; soft steel 0·111; wrought iron, 0·152; the ratios being the same. Hence the conditions that determine the conduction of heat and electricity are the same.

Henley's Price List.—We have received the new price list of Messrs. W. T. Henley's, Limited, relating to electric light cables insulated with indiarubber and with vulcanised indiarubber. Similar lists are given for lighted wires for internal work. These lists give not only the prices but other information relating to conductivity, diameter of wire, weight per mile, &c. Of course we cannot enter into any comparison of prices—that is the work of purchasers.

Digitized by Google

Otto Engines at Toulouse.—An installation has just been completed at Toulouse, which is noticeable from the fact that the motive power is supplied by two 50 h p. two-cylinder Otto gas-engines. These drive two 500-light dynamos, and supply light for the Theatre du Capitole of Toulouse. The lamps are supplied on two separate circuits, so that if one fails the other still partially lights the whole place. The installation has been undertaken by the Toulouse Gas Company.

Thomson-Houston Patents.—News has just reached us from the United States that the American courts have decided that the Thomson-Houston Company are in possession of the fundamental patent on the automatic regulation of dynamo machines, as against the so-called "American" and all other systems. Messrs. Laing, Wharton, and Down confirm this information, which will probably be followed by similar proceedings by the Thomson-Houston Company to protect their inventions in other countries.

Government Lighting at Washington.—The Interior Department at Washington has purchased, and is now putting in place, a Brush electric light plant capable of furnishing 800 lights. The plant will cost about £2,000, and will be operated by department employés. The cost of lighting the department building has hitherto been about £100 per month, £40 for gas and £60 for electric lights furnished by a local company. It is expected that under the new system the cost of lighting will be reduced more than one-half.

Electric Bulletins.— Mr. Patrick Delany has perfected an apparatus for use simultaneously in a series of offices, like the Stock Exchange "tickers," but which will give short temporary messages in actual letters. These are exhibited in a telegraphic frame, actuated by electrical devices, each controlling an alphabet, and the message thus appears in the spaces. A bell calls the attention of people in the office or members of the club, &c., where the apparatus is in use to the receipt of the message, which stays in sight until the next message appears.

Slow-Speed Electric Trains.—It is said that one of the attractions at the Paris Exposition of 1889 will be a railway train, consisting of 400 platform cars driven by electro-motors and running in a continuous circle. The line will be sunk so that the platform will be on a level with the surface; the train will run slowly enough to permit the ordinary train-catching person to step on and off while it is in motion, but for the accommodation of elderly and nervous people, a stop of 15 seconds every minute will be made to allow them to pass on or off or over the platform.

Suspension Electric Railway.—Mr. R. Clark Forsyth is the inventor of one of the latest schemes for electric suburban traction, and intends to try the system in Chicago. It consists essentially of overhead passenger cars swung from four wheels on the roof, which run on a single rail carried in the manner of a suspension bridge by a lattice of struts and ties. At each street intersection is to be a pier of structural ironwork, over the apex of which pass the suspension cables. The electric rail runs in a straight line suspended from this, and the car hangs in mid-air below this. Double lines would be provided for crossing.

Cables to India.—The Indo-European Telegraph Company notify that, in addition to the interruption of the Eastern Company's cables between Aden and Bombay, reported on the 11th of this month, one of the cables of the Indian Government between Bushire and Jask, in the Persian Gulf, broke down on the 13th inst. at noon. The Indian Government has now, therefore, only one working cable by the Indo-European route, and there is, consequently, heavy delay on messages. The Government repairing steamer, "Patrick Stewart," is on her way to the fault, and the repairs are expected to be completed between the 20th and 22nd inst.

Prizes for Electric Meters.—The Conseil Municipal of Paris have decided to hold a collection of the various kinds of electric meters, and have voted a sum of 20,000f. to be distributed as prizes, under the following conditions: 10,000f. to the inventor who produces a meter giving entire satisfaction; five prizes of 2,000f. to the five inventors whose meters, after this, show the most important progress realised. Where the meter is only applicable to one of the two forms of current, direct and alternating, only half of the prize will be awarded. The town of Paris reserves the right to manufacture the prize meters for its own use without further payment.

Lighting the Cars in the Tunnel.—The elevated railroad at Kansas passes through a tunnel, and a contract has been entered into with the City Electric Light Company to light the cars for the time only that they are passing through the tunnel. This is accomplished by means of automatic apparatus, which turns the light on when the cars enter and off when they leave the tunnel. On the top of the car is a V-shaped standard which comes into contact with a bare insulated wire strung through the tunnel, and is held in contact therewith by a spring. The standard leaves the wire when coming out of the tunnel, and the light, of course, is turned off.

Fire Alarm in Electric Stations.—A serious accident happened recently at New Orleans, where a sudden fire broke out through the dropping of a light in a bucket of oil, and put out all the lights, in many cases where no gas connections existed. It would seem an almost impossible thing to burn down an electric light plant; but the thing has happened more than once in America. A satisfactory arrangement would be to have an automatic alarm connected with the fire brigade in case such an accident occurred. In the case mentioned what made the matter worse was that the fire-alarm office itself was in darkness through failure of the lights.

Buckingham.—We are glad to see that the local electric light company has got to work in Buckingham. Sufficient shares having been applied for in the Buckingham Electric Light and Power Supply Company, the directors have decided to proceed with the installation at once. A few evenings ago they visited and inspected the Old Tan Yard, which is to be the central station, and took measurements. They also ordered the necessary machinery, steam-engine, and electric plant, and decided upon the structural alterations of the building. They hope to have several establishments in the town lighted up with the electric light during the next month.

Paris Electric Roads.—Electric traction for Paris is in the air. We have recently had the project of M. Berlier, which was for an underground railway, consisting of a cast-iron tube 18ft. in diameter, run without taking up the roadway from the Bois de Vincennes to the Bois de Boulogne. Electricity was to be used in this tunnel, the tube itself to constitute the return. This scheme was

Digitized by Google

rejected by the Paris Council. Now another scheme is being introduced to the municipal authorities to run a single-rail overhead road, also run by electricity, at the time of the Exposition of 1889, which is to connect a large number of the boulevards of Paris, and to have connection to the exhibition grounds in the Place du Trocadero.

Utilising the Force of an Artesian Well.—Instances are now fairly common where the downward force of falling water has been utilised to furnish motive power for driving dynamos, but to make the upward force of a fountain serve for this purpose seems a little out of the question. Yet this, nevertheless, is what is proposed to be done in the case of artesian wells. The first installation of this kind exists in Florida. The artesian well in question has a diameter of nearly 12in., and is about 500 yards deep, and ten million gallons of water per day rushes out of this aperture. A turbine-wheel is placed at the outlet, serving to drive a dynamo which lights the surrounding buildings, and the installation works with great success owing to the extreme regularity of the water supply.

Patents.—"It is an ill wind that blows nobody good," says the old saw, and our American contemporaries must be pleased with the various legal opinions on the battles fought in law courts over incandescent lamp patents, for the competing companies are largely advertising, each of course, claiming decisions in its favour and as pulverising its opponents. We are practically certain that the money spent over these lawsuits will never be repaid to the companies during the life of the patents. A good business maxim, and one to be commended, is that which says, "Keep on experimenting, take out a patent for an improvement that can be shown to be an improvement about every fourth year, let all your clients, and all who may be clients, know of the improvement, while ostentatiously dropping the previous manufacture. One word—don't make too much of your improvement before the old stock is run low, and the new stock ready, or buyers will reject the old in favour of the new."

Underground Telephone Wires.—Brooklyn, the aristocratic suburb of New York, has now a most complete underground telephone system, the whole of the wires being brought into the exchange entirely underground, and there are no fixtures of any kind on the roof. The conduits are of creosoted wood, with ducts two or three inches in diameter, and laid in banks of from four up to thirty-six when nearer the office. The company consider the durability of creosoted wood for conduit is thoroughly established, and their method of construction permits the handling of the cables easily, both in drawing in and hauling out. The arrangements of switchboards, &c., is very complete, and the substitution of underground wires has been carried out without many of the subscribers being aware of the change. There are at present 2,100 miles of wire placed in the conduits. The remainder of the poles on the outskirts of the city will be taken down and underground wires substituted during this year. The exchange has 3,581 subscribers, of whom 1,600 subscribers are on the underground service.

Charging Stations on the Thames.—Now the question of electric launches on the Thames, with their accompanying charging stations, has been mooted to the public and satisfactorily received, it may be well to make a suggestion which will tend, during the coming seasons, to make the method of pleasure-tripping both easy for the pleasure-seekers and convenient to the suppliers of energy. The proposal has been made to put up a number of floating stations, at one firm's risk, at different places up the river Thames. This may be possible, but we fancy a better way would be this: It is well known that from Richmond up there are a series of first-class hotels, which combine the business of boat-letting, luncheon-providers, and hotel. Tagg's Hotel is a sample one, and another very large hotel is being built on the island off Weybridge. Once the fashion for the quick-moving, silent, and comfortable little electric launches sets in—as it must soon—these hotels will be glad enough to cater for their customers for "electric energy" as for "cutlets and salad." A charging station at each of these hotels would be a convenient source of power for launches, and an additional source of income to the riverside hotels; and the plant necessary for this purpose could be utilised to provide the hotel itself with that most desirable and coveted of luxuries—the electric light, practically with the minimum possible cost.

Jointing Phosphor-Bronze Wires without Heat. The following abstract from the *Electrotechnische Zeitschrift*, part 4, 1888, is given in the *Journal* of the Society of Telegraph Engineers and Electricians, upon a method for jointing phosphor-bronze wires without any application of heat: "It is very desirable to avoid by all means the heating of phosphor-bronze wires, as this leads to a decrease of the breaking strain; and consequently some means of jointing had to be sought for which might replace the method of soldering used for iron wires. Moreover, experience has shown that some local action is set up between the tin solder and the iron wires, which in time leads to a weakening of the joint; such action would of course be still greater with phosphor-bronze wires, owing to the greater affinity of tin and copper. The best substitute for solder is a copper amalgam prepared as follows: Freshly precipitated copper oxide is heated in a tube in a stream of hydrogen until it is reduced to metallic copper. When thoroughly cooled, this fine copper powder is moistened with dilute sulphuric acid and well mixed with mercury, and is then washed. A simpler plan, though not such a good one, is to obtain the copper powder by reducing copper sulphate by means of metallic zinc. In making use of this amalgam for jointing wires, it is pressed closely round them and allowed to set. On this account a twisted joint is not very well adapted; a Britannia joint is better, as the amalgam penetrates inside the binding wire. But the best joint is made with a tube connection, the two ends of the wires being turned up at not too sharp an angle and secured with binding wire; the amalgam is then pressed well into the tube, where it sets quite hard."

Intercepting Telegrams.—The Austrian War Office, says the *Times*, is stated to be paying great attention to a matter which is of the greatest importance in the use of the telegraph in the field. It has been ascertained that the telephone is so acute of hearing that before it every secrecy of telegraphing disappears. If, formerly, it was desired to ascertain the secrets of the telegraph wire, the latter had to be cut and an apparatus inserted. Now, with the help of the telephone, all telegrams may be read easily, even from a considerable distance. It is only necessary to carry a telegraph wire of moderate length parallel to the original line, and insert in it a telephone, from which the Morse signs may be read off by the ear. This would, of course, be very awkward in the case of war telegrams. Even guarding the line would be of no use, for the enemy may, at a safe distance, say, half a mile from the telegraph line,

Digitized by Google

where he could not be seen, secretly set up his intercepting apparatus, consisting of a hundred yards of parallel wire and a telephone. The question has naturally arisen how this difficulty is to be met. The problem is solved in a surprisingly simple manner by Herr Heinrich Discher, who proposes cross telegraphing for the purpose. He says that, if telegrams are sent from opposite directions on the same wire at the same time, the listener at the telephone only hears a medley of confused sounds. In practice the matter may be dealt with in the following manner: One station sends actual telegrams, the other a despatch previously agreed upon. As long as the operator at the former station sees this despatch coming in, he may make sure that no eavesdropper is able to read the telegrams he is sending.

The Sprague System a Complete Success.—We finish to-day the interesting and exhaustive account of Mr. F. J. Sprague's electric road at Richmond. We announce at the same time the effect the success of these experiments have had in the substitution of the electric for a proposed cable system in England. The following is an independent testimony of the success of the Sprague system by the president of one of the street tramway companies of America, who have adopted the system of electric traction: "Wilmington, Delaware, June 14, 1888. The Sprague Electric Railway and Motor Company. Gentlemen,—I desire to express to you our entire satisfaction with the overhead system of electric propulsion of street cars as constructed by you on the Riverview extension of our line. The system has been in operation here for three months, and from a practical experience during that time we can pronounce it a complete success. In fact, we consider it by all odds the best and most economical mode of running street cars in suburban districts, or in any place where permission to erect poles can be obtained. In comparison with horse-power, we find it decidedly cheaper and more efficient in every way. It is popular with our patrons on account of its cleanliness, its smooth and rapid motion, and especially for the absence of the usually overtasked and labouring horse. Our road is quite hilly, and the cars, loaded sometimes with seventy passengers, climb with ease, at the rate of five miles an hour, a 5½ per cent. grade, having a 90ft. curve. The cars are 16ft. long, and each has been running continuously from the start sixteen hours a day, making 64 miles daily on the 1⅛ miles of our extension. At first, many persons here were sceptical about the successful use of electricity as a motive power instead of horses, but the practical demonstration made on our line has converted them, and directors, press and public have only words of praise for electricity, and endorse it as the future motive power for street car traffic. Each member of our Board fully approves the above statements.—Wishing you every success, I remain, yours, &c., William Canby, President Wilmington City Railway Co."

The Thames Subway.—At last we are to have a real working electric railway in London. The shareholders of the City of London and Southwark Subway Company, meeting last Tuesday afternoon at Winchester House, authorised the directors to make arrangements for working the line by electricity. The subway has been in progress for some considerable time, and, when complete, will connect the City side of London Bridge to the Swan at Stockwell, with intermediate stations underground. The line was intended to have been worked on the endless cable system which was said to have given very satisfactory results in America. Here, as is also now the case in America, directors of tramways are anxiously studying electric traction, and the absolutely convincing proofs of its superiority in point of ease, comfort, outlay, and cost of maintenance, have decided several American companies intending to put down cable lines to abandon that idea and to substitute the electric roads for these. This has been the case with the subway scheme, and from the statement of the chairman, the directors have satisfied themselves conclusively, after careful investigation, that the line can be more thoroughly, efficiently, and economically worked by electricity. Several eminent firms have, they say, expressed their readiness to undertake the work, the system which they propose to adopt being that of continuous conductors, and are so sanguine of success that they have offered to work the line on favourable terms for a number of years. One or two of the shareholders present at the meeting objected to the action of the Board in discarding the original idea of a cable for what, they considered, the more risky electrical system, but eventually the resolution proposed by the chairman was sanctioned. It was stated during the proceedings that the engineer hopes to get that portion of the subway between the City and the Elephant and Castle completed by the end of the year. We shall watch with interest the carrying out of this scheme. From practical examples we have before us in England, America, and elsewhere, there should not be the slightest difficulty in making this not only a practicable line, but a successful one financially, and we feel sure it will be the beginning of a series of similar undertakings where the tractability and cleanliness of this method of traction will be utilised for the public good.

The "Norham Castle."—The equipment of a passenger steamer is not thought complete nowadays without the luxury of the electric light, and not many of the ships of our mercantile steam-passenger service are now without the light. One of the latest additions is that of the "Norham Castle," one of the Donald Currie mail steamers to the Cape. This vessel has recently been fitted by the Brush Corporation throughout with electric light, comprising 332 incandescent lamps. The main saloons have 28 lamps with shaded globes, and the second and third-class cabins and quarters of the officers and crew are also lighted. Each passenger state-room has a 16 c.p. lamp with its own switch at the side of the berth, being arranged with the greatest convenience for passengers. The signal lamps are also illuminated by electricity in the manner described last week; and a submarine lamp is also fitted, by aid of which the propeller blade and any part of the bottom of the vessel may be inspected. There are two sets of electric plant—viz.: two Tangye-Archer engines, 9in. by 8in.; these run at the very slow speed of 200 revolutions per minute, and are coupled direct to two F2 "Victoria" dynamos by Raworth's patent flexible flywheel coupling. Each dynamo gives an output of about 11,000 watts at 100 volts. There are about 320 16 c.p. lamps in neatly designed fittings, and there are also three cargo lanterns, each fitted with four 16 c.p. lamps, making a total of 332 lamps of 16 c.p. each. These lanterns can be attached to any of the numerous connections along the deck, and by the aid of lengths of cable to each the whole of the upper deck can be illuminated when required for entertainments, balls, &c. In the engine-room, stoke-holds, and tunnel there are thirty strong fixed lamps, and four strongly-guarded portable lamps, with suitable lengths of flexible cable attached,

Digitized by Google

and there is no part of the engine-room, stoke-hold, tunnel, or coal bunkers that cannot be examined. The wiring is carried out entirely on the single-wire system, and every part of the wiring can be inspected should it be required. None of the wires throughout the ship are in any instance run behind panels, and in the first saloon all the wires are led on the surface of the mouldings and panels. None of the ship's mouldings have been interfered with, the wires being covered by special and suitable mouldings, designed by the Brush Corporation, to harmonise with the existing ship's mouldings, the whole presenting a neat and elegant appearance when finished.

Harold P. Brown and the Dog.—A young gentleman of the name of Harold P. Brown has been raising the dust in New York by his attack on alternating currents. He alleges that, practically, only direct current circuits are safe, and has drawn up a set of rules which he would like to see enforced by the Board of Control. He has been variously and vigorously sat upon by the electrical engineers all round. Last week, to demonstrate his theory, he made a public demonstration of the effect of various currents upon a luckless dog. His demonstration seems to have been carried out in the most haphazard, unscientific manner; connections were left to be made by twisting wires together, the condition of the dog was not stated, and the same dog was used throughout. Connection was made by twisting some wet waste round his right forefoot and left hindfoot, and the resulting resistance was announced as that "of the dog." No comparison was really effected, though the dog was eventually killed by an alternating current, for the same dog took the whole of the shocks—first with 300 volts continuous current, afterwards increased to 500, and then to 1,000, during which time the dog nearly strangled himself with his futile struggles. He was then given a shock of 330 volts, alternating current, which finished him off. The so-called demonstration has been made the subject of much ridicule by the technical press. Our contemporary, the New York *Electrical Review*, in describing the experiments, rightly stigmatises them as worse than useless, and says: "Had the order been reversed, and the alternating current been administered first, it is much more than probable that a final dose of 330 volts continuous current would have been quite as effectual to kill. It was much like pounding a man to jelly with a club, and then changing weapons and finishing him with a merciful bullet. Nothing is proved; but it would be a good thing if one of the wealthy companies authorised a series of conclusive experiments under proper conditions. If dogs are to be the subjects, let there be a fresh dog for every shock, and let the dogs be well fed and conditioned, and not a lot of poor half-starved vagrants from the pound. And, above all, let the tests be made in a true scientific spirit, which looks not to prove anything but the exact truth, and by a body of men who know the importance of making comparisons only under exactly similar conditions. Such demonstrations would be reliable, and their conclusions irrefutable."

Electric Expressage.— We notice that the *Street Railway Gazette* gives detailed drawings of Weems' electric expressage, which we have already noticed, a system by which papers and parcels are to be shot across the country at the rate of 400 miles an hour, reaching the Pacific from New York in nine hours. The whole idea is American in its daring, its immensity, and also in its necessity. The interest on valuable bonds of thousands of dollars' value is worth saving when the passage takes three days, but in England, what with the Great Northern accelerations of London to Scotland in eight hours, such extremes of swiftness are hardly so necessary. So we may let the Americans experiment with newspaper projectiles. The designs show a low car, like a huge shuttle, mounted with six wheels, two at each end and two along the centre at the top. This car is to run on a strong overhead frame carrying single or double sets of rails, and can be carried across country in a straight line. The Electro-Automatic Transit Company of Baltimore has been incorporated to carry out these designs, with a strong board of directors, and the enterprise, we are assured, is no longer only a "scheme," but has assumed a practical shape, and a line is to be built at once from Washington to Baltimore. "It has created an intense interest," says their report, "in scientific and railway circles, and it has been pronounced eminently practicable. It bids fair, at an early day, to revolutionise the world on the question of rapid transit." It is curious to note the way in which electric marvels follow each other; scarcely has one apparent impossibility been brought before the world, disbelieved, laughed at, carried out and become useful, than another comes to take the breath away. It is proposed also to institute a similar quick delivery in towns in underground tubes, for delivery of parcels, newspapers, &c., but its greatest usefulness would be for cross-country work. "In the momentous question of the present age," the prospectus goes on to say, "which is the struggle for the mastery over time, the use of electric force is making such strides and attracting such attention in the world of mechanics, as to render its general adoption in all cases where power is necessary merely a question of time. By the use of this force, intelligently handled, rapid transit can be readily obtained in its fullest meaning, and if time is money, it holds good that money will also be saved. A handsome sum per day was offered by a clearing house and a number of merchants in one of the large western cities for a train saving eight hours, which would have saved one day's interest on exchanges, but the road was unable to accommodate them. The use of electric force has been brought to bear upon this particular subject in the system herein treated of, which will be found to be not only feasible, but eminently practicable." This lightning railway is to consist of a light structure, elevated some 20ft. from the ground. A permanent generator, of prescribed horse-power, is to be located at each end of the line, from which the current will pass to the conducting rail, and will be immediately taken up by the travelling motor, to which one or more cars can be attached. On approaching its destination, it will pass a certain defined point where the electric current will be cut off, leaving the train to its own momentum, which will gradually decrease. Each car then will encounter a trip lever, located at a sufficient distance from the stopping place, which will spring the brakes in succession, bringing the train to a standstill at a designated point. The cost of such a railway is figured out to be the exact sum of £1,016 per mile for a double track, and £670 per mile for a single track. It has, of course, been suggested that passengers may even be eventually sent over these lines, possibly in a recumbent posture at the rate of several miles a minute. The feeling such an idea inspires will give us a very good idea of the feeling with which our forefathers regarded the introduction of modern railways. Whether this is also possible, time alone will show.

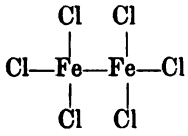
THE CHARGE ON THE ATOM.

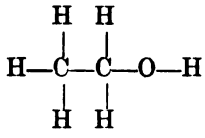
BY J. ENRIGHT, B.Sc., LOND.

(Concluded from page 124.)

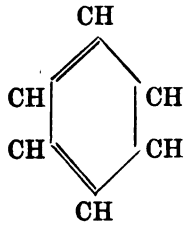
To return to the question of valency. The doctrine of "the charge on the atom" undoubtedly gave the term a new signification. For a lifeless hypothetical bond it gave a hypothetical charge of electricity, and inasmuch as we know that an insulated charge of electricity is capable of doing work, the new conception is more satisfying. But the new and the old are not always at one, and as the matter is looked into the feeling of satisfaction does not grow. No difficulty appears with regard to the simpler cases, such as HCl, KI, $MnCl_4$, CH_4, CCl_4, PCl_5, &c., but take Fe_2Cl_6. The graphic formula indicates that the stability of the molecule depends upon the cohesion between the two atoms of iron.

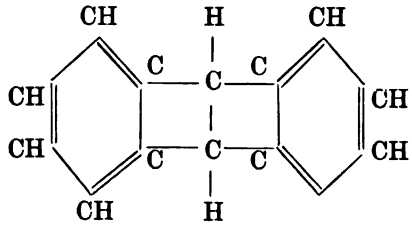


But the iron is understood to be charged positively, and the repulsion between atoms with charges of the same sign would rather tend to destroy the molecule than to keep it intact. This, as will be apparent to everybody, is a typical case. If there be anything in the point I have just raised, we are only on the very fringe of our trouble. Graphic representation has been of greater use in organic chemistry than in the inorganic branch of the subject, but the theory appears to reduce it to an absurdity. Consider the graphic formula of any one of the alcohols. Here we represent the molecule as kept in its integrity by the charges on the two carbon atoms, but as the charges on



them are of the same sign, repulsion, and not attraction, ought to result. If "the atom of every chemical element is always united with a definite unvarying quantity of electricity" (to use the words of Sir H. Roscoe), where are we to find "the mighty electric attraction" (Helmholtz) which is supposed to hold the atoms of the molecule together? The members of the open chain series became the most unstable things imaginable. But what of the "closed chain" series? Written graphically, they look explosive compounds. Examine the formula of benzene or anthracene, and say if anyone can fairly maintain that all the carbon atoms are charged and that the charges are of the same sign.





According to our theory, then, the "open chain series," the "closed chain series," the whole organic would—in fact, ought to—go to pieces, and no one can explain how it pulled itself together at first. Chemists who hold the Helmholtz theory must give up writing graphic formulæ as of yore.

The change of valency of elements constitutes another difficulty. Ferrous may be oxidised into ferric salts:

$$2\,Fe^{II}SO_4 + H_2SO_4 + Cl_2 = Fe^{IV}_2(SO_4)_3 + 2\,HCl.$$

In the ferrous salt on the left, the atom of iron is endowed with two monad equivalents of positive electricity. In the ferric salt on the other side, each atom of iron is attached to four monad equivalents of the same sign. I see no difficulty in understanding that an atom may hold twice or thrice as much electricity at one time as at another; but I cannot see, neither in this nor in similar cases, whence the increment comes. The chlorine and the sulphuric acid go in neutral, and the only source of electrification under the circumstances is the contact of the different substances. As I have already indicated, I believe that if the doctrine of "the charge on the atom" can be reconciled with facts, it will be through the friendly aid of the electricity of contact; but, even with this belief, I cannot devise any mode of explanation which can satisfy even myself of the increase in the quantity of electricity in cases of oxidisation. Further, if such an increase really took place, I consider that we ought to be able to detect it by means of the electrometer. I have allowed such oxidisation to go on in insulated vessels connected to one pair of the quads, the other being to earth, when the instrument was in as sensitive a state as I could make it, but without detecting any electrification.

Then again, the radical SO_4 is a dyad, and as such is endowed with two monad negative charges, yet we represent three of them containing six monad equivalents of negative as satisfying the eight monad positive equivalents of the two atoms of tetrad iron. Something will have to give way. Either the dyad nature of the SO_4, or the tetrad nature of the iron, or the theory.

There are many other difficulties of this kind which suggest themselves, but I don't see that much is to be gained by an accumulation of objections founded on the theory of atomicity, for if those already raised be well founded they appear sufficient.

I hope I am not disposed to take a narrow view of graphic formulæ and the system of bonds. I am satisfied with any view however lax and vague, provided there is left in it sufficient usefulness to enable one to understand isomerism in its many forms. Any modifying explanations which would wash such utility out of the system would, I think, render it useless, and to any form of it which retains such utility I believe the criticisms I have made would apply.

The theory which Helmholtz taught is of tremendous amplitude. It extends into physical science in all directions, but in the famous Faraday lecture only one side of it—one might say, only one facet of the great subject is dealt with. Nothing more, of course, could be done, and nothing could be more interesting and enjoyable than a treatment of the somewhat cranky subject of electrolysis by the great Professor; but can it be said that the facts of electrolysis were the best suited to test the theory which he proposed to expound? It would be ridiculous for one to pretend to lay down the law, but, judging from other cases, it would appear that it is the better known and simpler rather than the obscure and abstruse facts of a subject which supply the basis of a theory. At all events, no theory which does not give a ready explanation of the former can long survive. The electrolyte only is examined and examined only at one end of its career, at its destruction. But I submit that for the purpose of ascertaining whether or not a "charge on the atom" is essential to the existence of the molecule, a close scrutiny of its formation is as likely, if not more so, to give the desired information, and it is to this aspect of the question that I would now direct attention.

Helmholtz lays it down, as the following passages show, that when the ions are liberated from the electrolyte by the agency of the galvanic current, their charges are given up and they become neutral.

"At the surface of the electrodes decomposition can take place if there be sufficient E.M.F., and then the atoms give off their electric charges and become electrically neutral." And, again: "Hitherto we have supposed that the ion with its electric charge is separated from the fluid. But the ponderable atoms can give off their electricity to the electrodes, and remain in the liquid, being now electrically neutral."

It is unnecessary to quote further as his ground appears to be most clearly defined. Now, as the ions on liberation, by the action of the current, become neutral, and as the very existence of a molecule requires that the ions composing it shall possess a charge, it follows that at the formation of a molecule some machinery must be at hand to produce the indispensable electricity—a supply of positive for the

Digitized by Google

cation, and a supply of negative for the anion. The difficulty of proving a negative is very great, and I am bound to admit that I cannot prove that such machinery does not exist. On the other hand, no one has detected such machinery—at least, as far as I can ascertain. I have myself, as already stated, vainly endeavoured to detect electrification during the formation of salts, but I recognise that such a thing may conceivably go on without its admitting of detection.

However, although we cannot be sure on this point, it is easy to deprive the region in which a salt is being produced of all positive or of all negative electricity, and so according to the theory to prevent or arrest the formation of molecules. Let an insulated hemisphere or cylinder of zinc be connected to the prime conductor of a Holtz's machine, and let it, by continuous working of the machine, be kept strongly charged negatively while a drop or two of dilute H_2SO_4 is dropped on it by means of a glass rod (insulating rod). The theory makes the formation of zinc sulphate impossible for want of positive electricity, but effervescence takes place, and the sulphate is undoubtedly formed. It is difficult to see how any charge of positive electricity that may by any known or unknown means be developed on the zinc can do other work than that of neutralising a portion of the negative charge on itself and the conductors connected to it, as long as the prime conductor and the zinc are kept negatively charged by continuous working the machine. If this be so, according to the theory no molecule could be formed. The only difference noticeable between the experiment when made as described and when under no electrical influence is that the effervescence is more violent (in the former case).

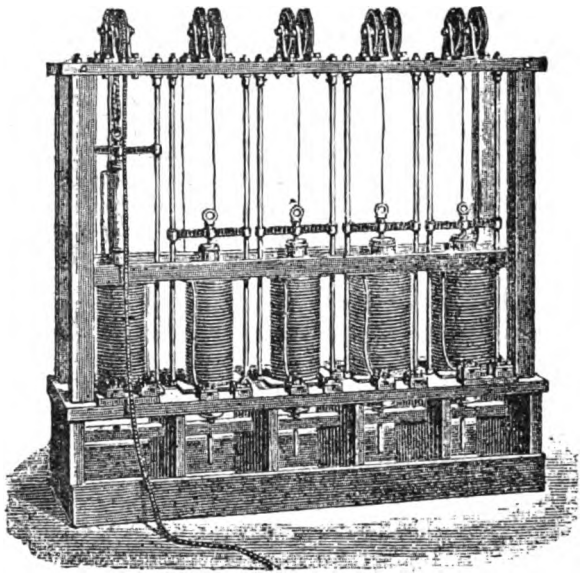
There appears yet another simple means of deciding the issue. A solution of cupric nitrate is easily electrolysed. An E.M.F. of less than three volts is ample to deposit copper from such a solution. Any E.M.F. exceeding this which can be used to keep copper and nitric acid apart, ought to prevent the formation of the molecule $Cu(NO_3)_2$. In order to apply this test the current from six Bunsen's cells was passed through strong nitric acid, the positive electrode being platinum, the negative a strip of copper. Gas was freely disengaged from both electrodes, which were about one inch apart, and the liquid rapidly became blue. In this experiment the whole force of the current tended not only to keep the copper in its integrity, but to cast any metallic impunity in the acid on the copper, and if, according to Helmholtz, there were only the electric forces to cause the ions to combine, cupric nitrate could not possibly be produced. This experiment was varied by covering the copper electrode with paraffin, except a part of that surface which directly confronted the platinum electrode, but, as had been expected, the result was the same.

In conclusion, I wish to point out that the theory of "dissociation" appears to be discredited by the facts and arguments by which it has been tested. The tardy precipitation from certain mixtures which are electrolytes, and therefore have a quantity of randomly moving oppositely charged ions traversing them, the hastening of precipitation from such mixtures by the agency of the galvanic current, the more rapid precipitation from the same mixtures when more concentrated, and therefore traversed by less rambling ions (according to the orthodox), are all decidedly against it. Then it derives no support, but rather the reverse, from the argument founded on the heat of combination of ions, which might be expected to cast light on the subject, and, lastly, no sudden fall of conductuity arising from an increase of current, which may on the theory be expected to occur in electrolytes, has been observed.

The objections set forth to the teaching of Helmholtz have been suggested from time to time by attempts on my part to explain by means of the "charge on the atom" and contact electricity common chemical facts. The case of catalysis given is the only instance in which it has been in this way effective. Many attempts to get some evidence of the atomic charges were made, but without success. This, of course, proves nothing. Helmholtz, however, represents chemical affinity as no longer a thing *sui generis*, but as the result of the attractions of oppositely charged ions, and this view, I submit, is positively disproved (1) by the experiments made by myself as well as by one cited from Prof. Lodge, and (2) by the admitted position and arrangement of atoms in the molecule, particularly in the organic molecule.

SELF-INDUCTION REGULATOR FOR THEATRE LIGHTING.

The conditions of incandescent electric lighting in theatres differ from those of ordinary house-lighting in that a necessity exists for raising and lowering the brilliancy of the lamps for obtaining stage effects. With gas, there is no difficulty, as all that is necessary is to turn the gas-tap supplying the foot-lights and other branches, and, with a fairly long handle, this simple method of regulation is quite sufficient. With the electric light, however, the matter is not so simple. The method hitherto adopted has been to insert resistances composed of lengths of iron or german silver wire in the circuit, which, by means of a movable contact allowing a longer or shorter length of wire to remain in circuit, absorbs some of the energy, which is converted in heat in the resistance. This method, though fairly convenient, being at present in use in many places where the light requires turning up and down, has yet several disadvantages. Among these are the facts that the resistance for any important installation have to be of



New Self Induction Regulator.

a considerable size, and space is by no means always available on such a crowded situation as behind the scenes of a theatre. Added to this the absorption of the energy gives out a certain amount of heat, which, when a large number of lamps are turned down, is difficult to get rid of, and is not without its own element of danger. This, of course, can be guarded against, and good ventilation can be assured to the resistance, so that this method of regulation is very commonly in use. The most serious objections to it arise from the fact that if a resistance is used to lower the light, a certain amount of electrical energy is wastefully expended, and when a system of grouping in series is used for lowering the light, the scenic effect is considerably interfered with by the sudden alteration of the lamps. The question of wasteful expenditure is more important in those cases, which are now likely rapidly to extend, where the power is not supplied by a private engine and boiler, but is paid for by meter from a central station distributing the power by means of alternate-current transformers.

A method of regulating the candle-power of incandescent lamps for theatres and other similar places under these circumstances by means of self induction coils has been designed by M. Picou, manager of the works of the Compagnie Edison at Ivry, and is described in *La Lumiere Electrique*. It has been in use at the theatre at Nancy for some time, and has performed its requirements during the last winter season with perfect success.

This arrangement consists of a coil which is interposed in

Digitized by Google

the circuit in such a manner that its self-induction will cause currents of an opposite nature to the main current to circulate in the lamp circuit, and will decrease the current flowing, and in this manner diminish the light of the lamps. A series of self-induction coils of a moderate size will thus replace the large resistance coils to regulate the whole of the theatre lamp circuits. Each coil is composed of a ring of zinc, upon which the wire is wound. The coils are placed vertically, and are about 11in. in height; the diameter of the ring varies in the different coils. A core, made of a bundle of soft iron wire 2mm. ($\frac{1}{12}$th inch) diameter, and 16in. in length, is placed in each coil, and is regulated by counter-weights to vary the strength of the reverse current. The self-induction is greatest when the iron-wire core has a symmetrical position in the coil, with 2½in. showing at either side.

The management is extremely simple, and entirely does away with the suddenness of the alteration of the light experienced in a series-switching arrangement, and often also with resistance stands. The light is quietly and evenly lowered by altering the position of the core, and the regulation is all that could be desired. At Nancy, the regulator is placed on a wooden stand against the wall separating the stage from the saloon, and immediately below the theatre switchboard. It is thus directly under the eyes of the electrician.

The sole inconvenience that has been noticed is a slight humming of the bobbin, which is greatest when the core is farthest in. This noise can just be heard on the stage, but not at all among the audience. It is exaggerated probably by the fact that the coils are mounted upon a wooden case, which forms a kind of sounding box, but the inconvenience is so slight as not to have been found necessary to alter.

ELECTRIC WELDING AND ITS PRACTICAL APPLICATIONS.

An address was recently delivered before the Boston Electric Club, by Otis K. Stewart, on electric welding, as follows:

The history of electric welding extends over a much longer period of time than is generally supposed. Some eleven years ago Prof. Elihu Thomson, who then held the chair of Chemistry and Mechanics at the Philadelphia Central High School, was delivering a course of lectures before the Franklin Institute of that city, and among other experiments by which he intended to prove the substantially identical nature of electrical energy under any and all circumstances, he reversed an ordinary Ruhmkorf induction coil, showing thereby the difference of potential between the current in the primary and that in the secondary of the coil. In performing this experiment he brought the terminals of the coarse secondary winding of the coil into contact, and was surprised to notice that a high degree of temperature was reached instantaneously at the point of contact—in fact, such a high degree of heat that the ends were stuck quite firmly together, the copper wire being actually melted, so that it required considerable force to separate them. Instantly the thought flashed through his brain—electric welding. Prof. Thomson was, however, very busily engaged in teaching and lecturing, and in developing the Thomson-Houston system of electric lighting for the next five or six years, and it was not until, in the regular course of manufacturing electric-lighting apparatus, it became an imperative necessity to discover some means of having more perfect joint in copper wire than could then be obtained, that his mind reverted again to the old experiment at the Franklin Institute, and electric welding became an assured art.

I should like, further, to call your attention to the fact that the discovery was made several years prior to the building of a welding-machine. Several years ago (I do not remember the exact date) the necessity for welding the ends of copper wires became so imperative, that Prof. Thomson designed and built a small machine with which to weld fine wires. The experiment with this apparatus were so very successful, that the inventor decided to build larger and better apparatus, and experiment further, with a view to welding, if possible, much larger pieces of metal. These experiments were also successful, and the invention has been much further developed in the past year or two than the general public can have any possible idea of.

The theory underlying or the principle involved in the Thomson process of electric welding is very simple, as indeed is most of the apparatus also. The Thomson process of electric welding consists simply in forcing through the pieces of metal to be welded currents of such large volume that these pieces can carry them without heating. Now, when the pieces are placed in abutment, the point of greatest resistance, as you all know, is where they make contact with each other, and it is of course at this point that the heat is first generated. The instant heat is generated at the point of contact, the resistance at that place enormously increases, and a consequent more rapid development of heat is the immediate result. The metals are consequently raised to a high welding temperature in a very remarkably short space of time, and upon a slight pressure being applied to force the pieces together, a perfect welding is effected.

The field that is open for the process of electric welding is surprisingly vast, and of course no one can tell where it will lead to. I think one of the most important reasons why electric welding is taking an important place so rapidly is that the heat generated by the current is the only absolutely pure heat known in the world. The blacksmith, when welding with either a gas furnace or a coal fire, is constantly running the risk not only of burning his metal, but of introducing into it foreign matter in the form of gases, which are very deleterious to the substances of either iron or steel, which are the principal metals worked by blacksmiths.

Now, the heat generated by the electric current is absolutely free from all foreign and harmful substances, and it is this fact, I think, which very largely accounts for the rapid advance of electric welding, so far as practical work is concerned. Of course, this is not the only reason. One very important reason is the fact that the heat effected by the current is under absolutely perfect control. Now, I do not mean to say that this regulation is nearly perfect, or that it is very perfect, but I state that it is absolutely perfect, for the reason that it can be made entirely and completely automatic. The heat can be begun, and a stop put on the apparatus which will control the heat perfectly.

Then, again, welding by the Thomson process is a much neater and quicker operation than welding by the ordinary method of forge or furnace. I might also say in this connection that no skilled labour is necessary to operate an electric welding apparatus. I have before my mind now one young man who came to us not knowing anything of the conditions under which different metals should be welded, and who in a very short time has become so expert in handling these machines that he can now, on the first trial, make perfect welds in any of the ordinary metals, and in almost all varieties of steel, including, although I say it with some reservation, even Mushet steel and manganese steel.

As I have already stated, the field for electric welding is so very broad, that I have been really much embarrassed in endeavouring to present the most interesting portions of it to you this evening. There are hundreds of applications of the process, and, under the circumstances, I do not think I can do better than simply cite one or two instances or examples of very small work, and then some of larger work. We are not limited, of course, in our work by the size of the pieces to be welded. We can weld the finest wires and the heaviest pieces. As an example of quite small, though not the smallest work, I might mention the welding of gold rings. We have succeeded in welding gold rings. I want to call your attention to the fact—that I say we *have* succeeded. It is no longer a matter of experiment, but the welding of gold rings by our process is an assured success. Now, what does this mean? It means, first, that we can make a better joint than is now made, doing away entirely with soldering, and in its place making a continuous gold ring; secondly, it means that the work is accomplished in about one-fifth of the time that it now takes to make a decent joint; and it means, lastly, that soldering material is saved, that an enormous wasting of heat is done away with, and that the dangers of burning gas are entirely obviated.

As an example of somewhat larger work, I might mention the welding of axes. There is, not very far from Boston, a manufacturing establishment which turns out about three thousand axes a day. Their axe is made of a body of ordinary wrought-iron, to which is welded an edge or face of fine tool steel, tempered and toughened. Their pieces of metal, before welding, have to be prepared somewhat in this manner. That is, a groove is cut in the body of the axe while a taper is cut on the face or blade, the latter being set into the former and the pieces welded in this position.

Now, in electric welding we do away entirely with this preparation, and I am very glad to say that without very much experimenting we have been able to entirely convert the engineer of this company to electric welding. He is now a firm believer that electric welding is the thing as far as the axe business is concerned.

As an example of much larger work, I might mention the welding of pedestals and locomotive frames. This is an entirely different class of work. The pieces have to be carefully prepared, a raised portion being left on the base or edge of the frame, and a taper groove being cut in the pedestal so that it may fit down over the raised portion referred to.

Digitized by Google

Some months ago I had the pleasure of being in Philadelphia, and while there of walking through the Baldwin Locomotive Works. This establishment is turning out fourteen locomotives a week. Now, what does this mean for electric welding? In the first place, on these engines there are some five or six copper rings, the wire composing which is of small diameter. The joints in these rings are at present made with a blowpipe flame, and it takes an expert some four or five minutes to make a single one. We can make them in as many seconds. There are also on each one of these locomotives at least one hundred and fifty joints in iron, from a half-inch area of section to several inches area. Now, it takes anywhere from four to fifteen minutes to make these joints by the ordinary process, and welding, you must remember, has been reduced to a very economical and accurate art in this establishment; but, nevertheless, we can do the work in at least one-fifth of the time which they now occupy. There are on each one of these locomotives four frames, each frame having on it at least two—sometimes three, four, and five pedestals. We will suppose that the average is three pedestals per frame. That makes twelve pedestals to the locomotive. To prepare the ends of the pedestals and the taper on the base of the frame takes some forty minutes. They have to be heated and hammered into shape while hot. After they are prepared they have to be reheated to a welding temperature, placed under a steam hammer and welded, this last operation requiring some thirty or forty minutes. You can easily see what this means. We allow twelve joints to each locomotive, and this makes 168 pedestal welds a week—168 welds which require at least one hour's time each.

In talking the matter over with the general manager of the company, I think we came to the conclusion that we could "beat this all hollow," the only question in his mind being whether the weld would be as perfect as at present. You will see that we would do away entirely with the preparation of these pieces, making a butt weld of the pedestal to the bit or expansion on the base. There are, of course, a large number of other applications, but I think that these three should be sufficient to indicate at least what the possibilities of electric welding are. There is one thing that I should like to mention finally—that we are able to make very durable, strong joints between metals of different kinds. For instance, these specimens which I hold in my hand consist of brass and copper welded together, and then twisted around twice. The joint held through this twisting, showing the strength. You will see that it is not even cracked.

What do we expect in the future for electric welding? We expect to be able to weld boiler plates. We do not say that we are able to do it now, but we have been thinking over the matter and experimenting, and we believe that this welding of boiler plates together is a thing of the not distant future. The same may be said of any metal plates. We expect also to be able to weld tubes in the length. I do not wish to be misunderstood. I do not say that we are now able to do this, but I do say that we believe it can be done. We are at present working upon apparatus of a light, movable character, which, without mechanical power, we believe will be powerful enough to weld line wire, such as telephone, telegraph, and electric light and power wires on the line. The apparatus can be put into a waggon and carried to any desirable point. The current obtained from storage batteries forms a portion of the apparatus, and the welding is effected on the line. We expect, also, to weld lead pipe in the same manner, so that any plumber can have a welding apparatus with which he can make one continuous lead pipe in mending and in building, doing away entirely with "wipe joints," and the expense attendant thereon. With an absolutely pure heat, with absolutely perfect means of regulation, with the heating constantly before the eyes of the operator, with a neatness to which ordinary methods cannot at all be compared, with an increased economy of, in all ordinary cases, at least 300 per cent., with absolute safety of handling apparatus—with all these advantages, I do not see why electric welding should not rapidly rise to the dignity of a most important and valuable art.

A paper on the same subject, by Otis K. Stuart, was also read at the recent annual meeting of railway telegraph superintendents, in which he says:

One of the advantages of electric welding, as practised by Prof. Thomson, is the localisation of the heat to the points or point at which it is desired, thus saving an enormous amount of energy which is usually wasted in welding with the forge or flame. So absolutely is the heat localised that pieces of iron 3in. long and an inch in diameter can be welded together, and then held in the hands for some time without any danger of burning, the only heat which is felt at all being that which is conducted along the metal to the hands after the welding is completed.

A further consideration of these facts will demonstrate that it is possible by the Thomson process to weld any metal, including even those which melt at a very low temperature, such as lead, zinc, and tin, and those which melt at enormously high temperatures, as, for instance, iridium, platinum, &c. Of course it goes without saying that we can weld any of the metals used in ordinary manufacture.

It is plain that as the heat is developed so rapidly, a very delicate means of controlling it must be provided, and we are glad to say that we have been able to provide arrangements for this purpose which are almost absolutely perfect—I am inclined to say absolutely perfect for the reason that the control of the current can be made entirely automatic.

We are able to take a bar of inch iron, 4in. in length, raise it to a dull red in 20 seconds, and hold it there for an indefinite period. To increase the heat to a bright red in a very few seconds and hold it there, then to still further raise the temperature to a welding or vapourising point in a remarkably short space of time. This indicates the delicacy of this apparatus, and I would add that no very great skill is required to operate the machine, a boy learning to weld iron and steel with great facility in a week or two. The time required to weld metals depends, of course, upon the power of the apparatus and the skill of the operator. We have made strong and practically perfect welds in half-inch round wrought iron in 6 seconds, in inch round wrought iron in 45 seconds, and so on. Experiments have proved to us that the power required to weld is proportional—or very nearly so—to the area of cross-section of the pieces. This is true of nearly all the metals, though, of course, the relative resistance and welding temperature of the several metals may interfere with this ratio.

For welding small wires, such as telegraph or telephone, and the smaller sizes of electric light and power lines, the power required is very small indeed, the momentum of heavy machinery being more than enough to effect the weld. In this connection I desire to say that we are now working to perfect an apparatus for welding telegraph, telephone, and electric light wire, and lines of pipe on the line. Our experiments in this direction have been successful, and we now think it possible to construct an apparatus which will be capable of being moved about by one or two men, which will make joints in wires correctly and durably, the energy used being supplied by storage battery or batteries, forming a part of the welding outfit. For repair work and in general construction it is our belief that this apparatus will be found very useful and effective. In fact, we hope to do away entirely with the ordinary solder and link joints used at present.

The policy of placing an apparatus on the market has been adopted for the reason that our patents cover not only the apparatus for electric welding, but the art or process as practised by Prof. Thomson. It is hardly necessary to add that by the same process we can solder and braze, and anneal and temper, and do other heating, local or otherwise, which cannot be done economically by present methods. All these operations can be performed with the same apparatus, though, of course, it is better to have machines especially constructed for particular work.

Mr. G. L. Lang, who read Mr. Stuart's paper, stated that he had seen one of these machines in operation when a bar of cast steel and one of copper were welded together. One would suppose that the metal most easily fused would burn away before the other was brought to a welding heat. This is not the case, however, and it is very simply provided against. The current is brought to the bars through clamps which grasp the bars near to the ends to be welded. Where copper and steel are to be welded together, the clamp is placed about 6in. back on the copper bar, where it is only about 1in. from the point of contact on the steel bar. In this case the heat is diffused through a large body of the metal which is most fusible, so that they are both brought to a welding point at the same time. The process is something really wonderful, and promises to revolutionise the ordinary method. The system is now in constant use at the Thomson-Houston factory in Lynn, Mass.

Composing by Phonograph.—Not only are we able to print by electric motor, but by the use of Edison's phonograph printers can now compose with its aid. A compositor on the New York *World* set up 2,000 ems from the dictation of Edison's new phonograph. Two small tubes were fitted to his ears and connected by a large tube with a phonograph. The latter was run by a small electric motor and regulated by a pedal attachment by which the motor could be started and stopped at the compositor's pleasure. The phonograph would talk off a sentence into the printer's ears, and then be stopped until he had put the words in type. This is very probably the most important function that the machine will be used for. One of the greatest difficulties experienced by literary men is the mere manual labour involved in putting down their ideas in manuscript.

THE
ELECTRICAL ENGINEER.

Published every Friday.
Price Threepence; Post Free, Threepence Halfpenny.
Editorial and Publishing Offices:
139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

'SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months.	6 months.	12 months.

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, ESQ., *President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of* W. H. WOLLASTON, M.D., F.R.S., *and on April 20th we gave that of* SIR HUMPHRY DAVY, F.R.S., *whose fame as an electrician is still more prominent than that of* WOLLASTON. *Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of* PROF. D. E. HUGHES, F.R.S.

SPECIFICATION.

It is well known that a large number of the more prominent business houses are being gradually fitted for the electric light. It is of the utmost importance in many of these places that a light should be obtained that is not deleterious to the goods which are on view, and this cannot be said of gas. In the early days of electric lighting the work was done in a different manner to what is expected now, but gradually there has arisen, just as in any other engineering work and building work, specifications to which the contractor is compelled to work. These specifications are becoming more and more perfected, and, so far as we have seen them, they are drawn out upon the lines usual in engineering work. A contemporary last week severely criticised a recent specification, but we think, in all fairness, when such an onslaught is made the reader should be in a position to judge for himself, and therefore the whole should be given so that the justness of the criticism upon special portions can be seen.

We have before us this specification for wiring which has lately been issued, and upon which tenders have been sent in, for the wiring of Messrs. Hampton and Sons' premises, and we have given in other pages portions of this specification—in fact, the whole of it excepting the attached schedule—and this in order to give our readers some idea of what is required in the wiring of such places, and also to add our testimony to that of others as to the inadvisibility of some of the clauses. There are certain clauses of this specification which require consideration, and, in our estimation, should not appear in future specifications. It is customary in submarine telegraph work, for example, and in a good deal of engineering work, to make the contractor responsible for a certain time after the work is finished, during which time the owner does not take charge. We believe the usual time in these cases does not exceed a month. It will be seen, however, that in this specification for wiring there is a clause as follows: "If, however, from hidden or from any other causes whatsoever, within the said period of twelve calendar months, it be found that the installation, or any part of it, in any of the buildings is not working efficiently, then it shall be in the power of Mr. Heaphy to refuse to pass such part or the whole of the aforesaid installation until it has been altered and arranged to work efficiently, and to his entire satisfaction, and this notwithstanding that the materials, work, and arrangement had previously met with his sanction and approval." This would seem to imply that the contractor for this work is responsible for its maintenance for twelve months—that is, it should be efficient during that period—and that it should be handed over to his successors at the end of that period also efficient. If this reading is correct, there is not much difficulty in

Digitized by Google

the matter, because the price in the contract would be charged for such maintenance, but we doubt, on considering the whole specification, if it can be read in such a way, and that the contractor would in all probability hand over the work at the end of the six or eight weeks allowed him for its completion. It is rather a large tax to provide for when hidden or any other cause whatsoever is to be taken into account. Suppose, for example, by some unfortunate means there was to be a fire, would the damage caused by this fire have to be replaced by the contractor, and would this form a part and parcel of his contract? It may be said that electrical engineering differs from other classes of engineering, and that some faults are very slow to develop and may not develop themselves within the short space of one month. We cannot help thinking, in the case of electric light engineering, that if faults do not develop in such a period they cannot be of very great importance.

There is another clause to which we should like to call attention, although this follows the lines of almost all engineering specifications, and relates to the question of arbitration. A good deal has been written and said on the subject, but opinions are divided, and the clause appears quite as frequently as it is altered. It will be seen from this specification that Mr. Heaphy is acting for Messrs. Hampton and Sons, and the contractor is to be paid 80 per cent. of the contract price within a week of receiving Mr. Musgrave Heaphy's certificate. So far there is nothing to complain about. It is, however, different when we come to the following clause: "In the event of any dispute or question arising between the contractor and Messrs. Hampton and Sons, or their representative, on any matter whatsoever connected with the work, or the interpretation or meaning of any part or the whole of this specification at any time during the progress of the work, or after the work has been completed, or after the before-mentioned twelve months has expired, then such question or dispute shall be referred to Mr. Musgrave Heaphy to arbitrate upon and decide, and his decision shall be accepted as final and conclusive by both parties."

Of course we all know that the engineer may endeavour his utmost to be perfectly unbiassed in case of dispute, and may be so, but it would be better, on the whole, if the arbitrator was in every case a perfectly independent person, who had had nothing whatever to do with the work in dispute. We have often had to maintain this opinion in the case of engineering specifications, and we certainly do not see why a specification relating to electrical engineering should cause a change of opinion. The great aim is to get the work done in as perfect a manner as our knowledge at the present moment allows it to be done, and it must be admitted, from the experience of the past few years, that the knowledge obtained in electrical work during twelve months may be of such a character as to hardly admit of an interested party viewing clearly what was absolutely just and right twelvemonths beforehand. We do not altogether agree with our contemporary in its remarks about inspection in connection with fire offices. It is well known that somewhat rigid inspection is absolutely necessary, and although it may not have been imposed in the early days of gas, the pity is that it was not so imposed. The gravest difficulties are likely to arise if latitude of opinion is permitted as to the stringency of this inspection. We ought all to be agreed, not because it happens that Mr. Heaphy was first in the field, but on principle. Just as one swallow does not make a summer, so will not the change of one or one hundred individuals of their policies from one office to another affect the question. The moment any licence is permitted to contractors, so soon will every detail of the arrangement be open to alteration, and one office may permit change here and there till the collective changes, if admitted into any one installation would make it very far from safe. We must have safety combined with certainty.

CORRESPONDENCE.

THE INSTITUTE OF MEDICAL ELECTRICITY.

To the Editor of The Electrical Engineer.

Sir,—As you and many of your readers have expressed considerable interest in this institute, the directors would feel obliged if you will allow me an opportunity of making known in your columns the reason why the opening of our London establishment has been so long delayed.

In the end of March last the directors proceeded to the appointment of medical officers, and, after consultation with the medical visitors, selected two distinguished London physicians well known in scientific circles for the great attention they have long given to the medical applications of electricity.

These gentlemen, however, happen to be, one a fellow, and the other a member of the Royal College of Physicians, and though they were personally willing, unexpected difficulties of a purely professional character have been encountered in connection with their acceptance of the post offered to them. The directors hoped at one time that a memorandum on the subject which was signed by ten of the leading men in the electrical profession, all being members of the council of the Society of Telegraph-Engineers and Electricians, and six of them being also fellows of the Royal Society, would have aided in removing these difficulties, but I regret to say that they are still unsurmounted.

I need hardly assure your readers that this unfortunate *contretemps* will in no way alter the character and tone of the institute; but that, being more than ever convinced of the need for such an undertaking, and of the good that may come from it, the directors will proceed with a medical officer who is not a member of the Royal College of Physicians.

These premises are now being fitted up rapidly with all the necessary apparatus, and the directors hope that they will be ready to receive patients in September. They think it expedient, however, to defer the formal opening until October, when they hope to gather their friends around them.—Yours, &c.,

H. Newman Laurence, Managing Director.

Institute of Medical Electricity, London, S.W.,
August 11, 1888.

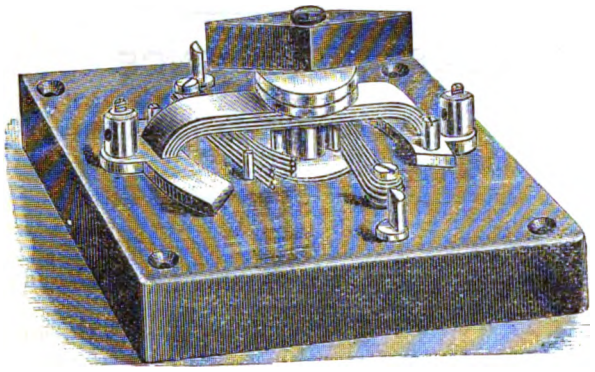
QUICK BREAK SWITCH FOR LARGE CURRENTS.

A modified form of Messrs. Woodhouse and Rawson's well-known "G" switch has lately been brought out, which appears to possess many advantages. The handle and contact-brush are not rigidly fixed together, although mounted on the same centre-pin; but two studs fixed in the handle-plate above the brush work in two segmental slots stamped out of a disc attached to the upper side of the brush, and these are so arranged that as the handle is turned in the "off" direction, the brush is driven by it nearly to the edge of the terminal contact-plates, when it is taken charge of by two sets of springs which effect a very rapid and complete break. These sets of springs each consist of several springs of steel wire formed up into "lock-spring" shape, and all mounted on one stud, the free ends bearing against a pin on the under side of brush. The plates of vulcanised fibre, which, in the older form of "G" switch, were fitted up for the brush to rest on when off the contact-plates are here done away with, so that the brush flies off the contact-plates quite clear of everything, and well above the slate base on which all the work is mounted. The necessary pressure between the brush and contact-plates is produced by a triangular spring washer in a recess underneath the slate base, which draws down the centre pin carrying the brush. The combination of the contact-brush of thin plates, the spring washer underneath, and the two sets of multiple springs, produce a particularly "sweet" motion; and the contacts made by the brush are evidently as perfect as can be desired. The good character of the free and quick break is also due to the combined effects of the very flexible springs and the spring washer underneath.



Messrs. Woodhouse and Rawson's "G" Switch.

The Woodhouse and Rawson Electrical Supply Company, Limited, state that these switches are made to carry 5, 10, 20, 30, 60 and 100 amperes, the three smaller sizes being rather different in construction from the others; and that very shortly switches on this design, to carry considerably larger currents, will be in the market.

We may add that these quick-break "G" switches are, like the older pattern, strongly made, and amply large enough for the currents they are intended to carry.

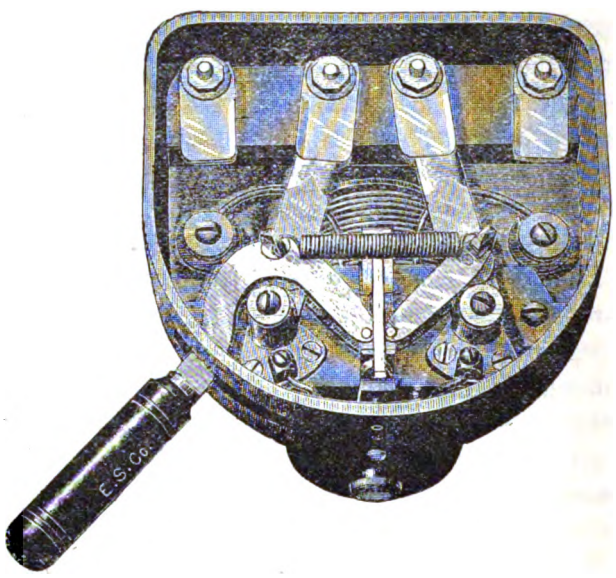
AUTOMATIC GROUND SWITCH.

An arc light circuit or a series incandescent circuit very seldom consists in a single straight run, but usually consists of a series of loops from the main line covering the area lighted. A ground connection on one of these loops will, if there is the slightest tendency to a ground connection at any other position, however distant, destroy the insulation, and put out all the lights, possibly also doing damage by fire.

An automatic ground switch is being introduced by the Electrical Supply Company, of Chicago, which is designed for use in high-tension series circuits to act automatically so as to cut out the damaged loop immediately a ground connection develops itself, thus preventing damage in this section, and at the same time allowing the lamps in the remaining sections to continue alight. The automatic action is so perfect that no spark is seen even at the point of ground. This has been demonstrated by coupling the switch experimentally at the station, and making intentional ground connection. The insulation of the switched-off loop from the active line is, moreover, quite perfect, and repairs can go on without delay or danger. One of the principal advantages is that the switch indicates which section is defective, and much searching for the ground is obviated, as well as the awkwardness of a total stoppage of the circuit.

In the illustration a spring will be seen which connects the two outer extremities of a knee and toggle-joint system of levers which are disconnected from the switch arms, the joints of which are brought by the direction of the handle almost exactly into line, and in the best position to easily resist the action of the spring. A catch is provided to hold the system of levers in this position; this is released automatically on development of a ground. This catch cannot be jarred out of position no matter how severe the concussion. The contacts are double-lipped, and offer no resistance to the passage of the current. The two outer terminals at the top are the loop-line terminals; those sunk in the body of the switch immediately below them are the main line terminals. The handle is for reconnecting the loop line after repair.

The body of the switch is entirely out of circuit, and is made as far as possible moisture proof, being covered thoroughly with a special heavy coating of gutta-percha and japan. The interior portions are thoroughly insulated and covered with a preparation of asbestos, conforming



New Automatic Ground Switch.

throughout with fire office regulations. The small button shown is for the purpose of cutting off the loop by hand by merely pushing it. A padlock attachment, not shown in the cut, is also provided by means of which the switch may be locked when cut out, so that no one can succeed in throwing it on while men are working upon the loop.

COPPER STEAM PIPES FOR MODERN HIGH-PRESSURE ENGINES.*

As might have been expected, the disastrous explosion of the main steam pipe and consequent loss of life that occurred on board the Royal Mail steamer "Elbe" in September last, and a similar explosion on board the North German Lloyd's mail steamer "Lahn," have led to investigations as to the cause of these accidents; and, further, the whole subject of the manufacture of copper steam pipes has been considered generally, and experiments carried out with the view of ascertaining the behaviour of the different kinds of commercial copper under various conditions of treatment and at various temperatures. A

* Paper read at the thirtieth session of the Institution of Naval Architects at Glasgow, July 25, 1888, by Mr. W. Parker, chief engineer surveyor to Lloyd's Register of British and Foreign Shipping, member of council.

Digitized by Google

summary of the investigations and the results of these experiments will not, I think, be without interest to these meetings.

The s.s. "Elbe" was built in 1870 by Messrs. J. Elder and Co., and fitted with ordinary compound engines. In February of last year she was placed in the hands of Messrs. Oswald, Mordaunt, and Co., of Southampton, for the purpose of being fitted with new boilers to work at a pressure of 150lb. per square inch, and of having her compound engines converted into triple-expansive ones. This work was completed, and the vessel was running her official trial in Stokes Bay, when the main steam pipe abreast of the after boilers burst, and all in the stokehole at the time, numbering eleven persons, were killed by the sudden outrush of steam.

The s.s. "Lahn" is a new vessel built by the Fairfield Shipbuilding and Engineering Company last year. In March last, while on her second voyage across the Atlantic, her steam pipe burst in a somewhat similar manner, but the loss of life was less in this instance than in the case of the "Elbe."

It was natural to suppose that the bursting of copper steam pipes, such as those of the "Elbe" and the "Lahn," would be found to be attributable to defective workmanship or material, and that due care had not been exercised in the manufacture of the pipes; but these investigations go to show that elements of very serious danger enter into the ordinary methods of making brazed copper pipes, especially when intended for high-pressure steam.

The steam pipe which exploded on board the "Elbe" was 9⅜in. in diameter inside, and 6ft. 6in. long, the thickness of the copper was ·276in., corresponding to No. 2 imperial wire gauge; it was brazed in the usual manner, with a lapped joint, and to all appearance seemed a well-made pipe. The copper had been obtained from a first-class manufacturer in Birmingham, and analysis has shown it to be chemically of the best quality.

The pipe itself had been tested by hydraulic pressure on two occasions, once for the satisfaction of the builders to a pressure of 300lb. per square inch, and a second time by the owner's representative to 350lb. per square inch. These tests had been sustained in a perfectly satisfactory manner, and, so far as could be judged, every care had been exercised by the makers to produce as good a piece of workmanship as possible.

Test-pieces were cut from the exploded pipe, and the copper away from the locality of the brazing was found to have an ultimate tenacity of 33,000lb. per square inch, with an elongation before fracture of 33 per cent. in a length of 5in., so that the bursting pressure for this pipe, in its cold state, should have been about 1,940lb. per square inch, being thirteen times the working pressure, or, taking the actual thickness of the copper at the fracture as measured after the explosion, and which was found to be $\frac{3}{16}$in., the pipe should still have borne an ultimate pressure of 1,220lb. per square inch, or 8·8 times the working pressure.

In order to ascertain the actual strength of the portions of the pipe adjacent to the exploded part, a piece of the pipe, about 30in. long, was cut from the portion still intact of the length which exploded, and two other similar pieces were prepared from the next adjoining length of pipe. These short pieces were fitted with flanges and tested to destruction by hydraulic pressure, and in each case the pipe burst in exactly the same way, namely, through the copper near and parallel to the brazed seam, commencing near to one of the flanges.

The pieces taken from the same length where the explosion had occurred gave way under a hydraulic pressure of 780lb. per square inch, the fracture exhibiting a granular and in part a discoloured appearance.

Of the two pieces cut from the next adjoining length of pipe, one burst at 600lb. per square inch with the same granular and partly discoloured fracture, as if the metal had been injured or partially cracked through during the operation of brazing; and the other burst at 1,140lb. per square inch, the fracture being granular but not discoloured.

This great diversity in the bursting pressures for pipes of the same dimensions and material, and the similarity in the character and position of the fracture in each case, together with the fact that the pressure at which the strongest of these lengths burst was still not more than five-eighths of the calculated bursting pressure, seemed clearly to indicate that the material had been injured in the neighbourhood of the seam by the operation of brazing.

Some very careful experiments to ascertain the effect of increased temperatures upon sheet copper were made by the Franklin Institute in America as long ago as 1837, when strips of copper were pulled asunder in a properly designed machine at temperatures ranging from 122deg. to 1,332deg. Fahr., and, as will be seen by the following table, the falling off in strength as the temperatures increased was very considerable, until at 1,332deg. Fahr., or a bright red heat, the tenacity was *nil*.

Experiments made at the Franklin Institute, America, in connection with an investigation into the strength of boilers.

Temperature above 32deg.	Diminution of strength.	Temperature above 32deg.	Diminution of strength.
deg.		deg.	
90	0·0175	660	0·3425
180	0·0540	769	0·4389
270	0·0926	812	0·4944
360	0·1513	880	0·5581
450	0·2046	984	0·6691
460	0·2133	1,000	0·6741
513	0·2446	1,200	0·8861
529	0·2558	1,300	1·0000

These results were substantially corroborated by a series of experiments made by Dr. Kirk and myself after the "Elbe" explosion.

From the table it will be seen that at 360deg. Fahr., or the temperature of steam of 150lb. pressure, copper has about 15 per cent. less tensile strength than when cold. But allowing for this falling off in tenacity, the steam pipe of the "Elbe" at 150lb. steam pressure should still have had a factor of safety of 8½.

Carefully examined through a microscope, the difference in the structure of the copper in the neighbourhood of the brazing where the exploded pipe and those afterwards tested gave way and the structure in that part of the pipe away from the brazing was very marked, and was clearly to be ascribed to the heating of the copper during brazing.

Test-pieces were cut from the pipe near to the brazed seam where the rent had occurred, and it was found that whereas the copper from other parts of the pipes showed a tenacity of 33,000lb. per square inch with an elongation of 33 per cent. in 5in. and 59 per cent. contraction of area as recorded above, in these pieces the tenacity was only 24,418lb. per square inch, the elongation only 4·6 per cent., and the contraction of area at the fracture only 13 per cent. This result was amply confirmed by testing other strips cut from the same locality; they each showed that the copper near the brazing had lost its ductile qualities and much of its tenacity.

In order to obtain further information on this point, the following experiments were made:

1. A strip of good copper was cut from a sheet and bent and broken cold.

2. A similar piece was raised to a heat above that necessary for brazing, when it became red, short, and broke with its own weight.

3. A piece was raised to the same bright heat as No. 2, allowed to cool, and then broken cold.

4. A piece was raised to the above brittle heat, at which it was partially broken through, then allowed to cool, and the fracture completed when cold.

The appearances of these fractures were very interesting; the first had the fibrous silky appearance of a good copper; in the second piece the fracture was coarse and blackened by the heat; but the third specimen seemed to have almost completely regained its tenacity and ductility on cooling, the copper in its normal state having a tenacity of 35,212lb. per square inch with an elongation of 40 per cent. in 5in., and a contraction of area at the fracture of 39·9 per cent.; and the third specimen, although it had been raised to a blistering heat, was, when cold, found to have a tenacity of 31,337lb. per square inch, with an elongation and contraction of area at fracture practically the same as the

Digitized by Google

normal copper, which would appear to show that, although the copper should be overheated in brazing, if not otherwise injured, its qualities will be substantially regained on cooling.

The fourth piece was partially broken while hot, and the appearance of that part of the fracture was discoloured by the action of the heat, but the part that was allowed to cool had its ductility restored, and afterwards broke with a bright fracture. This experiment was repeated a number of times, with similar results, and the fractures corresponded exactly in appearances not only with that of the exploded pipe, but also with those of the other pipes which were experimented upon, and which burst at pressures of 600lb. and 780lb. per square inch respectively.

The only difference in these fractures was the depth to which the partial crack, as shown by discoloration, had extended.

In this manner the exact appearance of the fractures of the exploded pipe, and of those experimental pieces which burst at the low pressures, was reproduced artificially by burning the copper and treating it in the way described.

From this it will be seen that, should a copper pipe be overheated during the brazing operation, and seeing that the metal becomes perfectly brittle at not much above the brazing heat, the pipe might accidentally be cracked when in this brittle condition; and, although the section of metal still remaining intact might be sufficient to sustain the cold water test pressure, yet the hot steam and accompanying strains might develop and deepen the crack, and the pipe ultimately give way at the working pressure.

This I consider to be the true explanation of the explosion of the "Elbe's" steam-pipe, and also that of the s.s. "Lahn."

A serious element of danger is thus shown to exist in the present practice of brazing large, heavy copper pipes intended to be subjected to the high pressure now so common. It is generally admitted that welds or brazed joints in any material must possess certain elements of uncertainty, and the above experiments show this uncertainty to be greatly increased in the case of copper worked over a fire.

How to eliminate these elements of danger becomes an important question. Various alternatives suggested themselves, as, for instance, that the copper might be worked cold and the joint made by a riveted seam, that brazed pipes might be served with wire or have strengthening bands fitted at short intervals (both of which systems I find are now resorted to), or that steel pipes might be used, the seam being riveted.

While these points were under consideration, I had brought to my notice by Mr. W. Elmore a method of making copper pipes of any required diameter, length, or thickness by electro-deposition, and I was instructed by the Committee of Lloyd's Register to proceed to Mr. Elmore's works and witness the operation of making these pipes, with a view to reporting thereon for the information of the committee. The process is briefly as follows: A mandrel is surrounded by ordinary unrefined Chili bars arranged upon strong supporting frames in a depositing tank of sulphate of copper, and the copper is dissolved or decomposed, as will hereafter be explained, and is deposited in the form of pure copper on the revolving mandrel, leaving the copper in the form of a shell or pipe, of any thickness required, fitting closely to the mandrel. When the required thickness has been deposited, the pipe and mandrel are exposed to the action of hot air or steam, then the copper expanding more than the iron admits of the mandrel being drawn, leaving the copper in the form of a pipe, without a seam, perfectly round and true both internally and externally; or the pipe may be expanded or made larger by rolling or other mechanical means, and then the mandrel withdrawn.

The deposition of copper by electricity is not at all new. It has been in use for years for electrotyping purposes, and for separating copper from its impurities, and particularly for extracting gold and silver. But copper thus refined is wanting in cohesive properties, and without some means of increasing its density, which would give to it, at the same time, both tenacity and ductility, it would in such a form be useless for mechanical purposes. The ingenious manner in which this difficulty is overcome by the present process constitutes its most important feature.

(To be continued.)

THE SOLUTION OF THE MUNICIPAL RAPID TRANSIT PROBLEM.*

BY FRANK J. SPRAGUE.

(Concluded from page 128.)

In estimating the road expenses, more than liberal allowance is made, but in a new enterprise it is safe to err on this side rather than attempt to claim for a system advantages which will not in practice be borne out. The expenses are then as follows:—

Oil, grease, and waste	$4.50	
Brushes	3.00	
Trolleys	2.80	
Material		$9.50
Three mechanics and one helper for thoroughly overhauling motors once a week, making repairs, adjusting brakes, &c.	7.90	
Four inspectors, two day and two night, for oiling machines and looking after brushes	7.50	
Two night inspectors to thoroughly inspect motors after cars are laid up and see that all bolts, nuts, and connections are tight, and that everything is in good working order for the morning run	4.00	
One winder and helper for making any repairs which may be necessary and any testing which is required	3.50	
Two linemen	5.00	
Labour		27.90
Depreciation on car work at 15 per cent.	18.00	
Depreciation on line work at 10 per cent.	4.00	
Depreciation		22.00
Total road operating expenses		$59.40

or $1.98 per car, making 80 miles.

The total motive-power expenses, both in the central station and out on the road, would not then exceed 3dols. 46c. per car making 80 miles, or 4·32 cents per car mile; and this includes everything except the executive and salary expenses, taxes and insurance, and is less than 40 per cent. of the cost of operation by horses with the same number of cars and under the same conditions.

But the showing is even better than this, for another fact is to be noticed, and it is an important one from an economical point of view. For example, 20 cars on duty for about 18 hours make a mileage of from 1,500 to 1,800 per day; and if it were not for the fact that the schedule requires them to operate part of the time on a single track with insufficient turnouts, they could make 1,800 or 1,900 steadily—this notwithstanding the fact that the speed is limited by municipal regulations. Many of the cars often run 90 to 100 miles. The same mileage and intervals made by twenty electric cars could not, under the circumstances, be made by anything less than twenty-five horse cars of the same size, and electric cars probably carry in the aggregate just as many passengers. It follows that to get the same service with horses not only would the number of cars have to be increased, but likewise the number of horses, conductors, and drivers. The same mileage performed by horses without these cars and grades would require a stable equipment of not less than 300 horses.

With the mileage which is now made there is an actual saving of about 125dols. per day in the motive power expenses as against operation by horses. It is hardly necessary to point out that this would pay a good interest on a pretty large investment. The capacity of the road to economically carry passengers has been made so apparent that the old City Railway, which was operated by mules and has about 13 miles of track and 50 cars, has been bought up and is to be equipped with motors operated from the same central station. A third line will probably be added, and in the near future every street car, to the number of 100, in Richmond, Manchester, and Virginia, will be electrically operated from one station.

* Read before the American Institute of Electrical Engineers, June 19th, 1888

Digitized by Google

From this same station is operated a power and light circuit.

A good idea of the operation of the system may be obtained from the following weekly table, taken from the records of the railway company up to the present date:

Week ending.	Number of cars put out for regular service.	Average number of cars out per day.	Miles per week.	Average miles per day.	Average miles per car per day.	Passengers per week.	Average passengers per day.

Having thus seen what is possible on a street railway, let us briefly consider the application of electricity on a larger scale.

The failure of the elevated railroads in this city to meet the issue of rapid transit is in no way more forcibly illustrated than by the number of plans which have been brought forward for discussion. No less than eleven have presented themselves, several of which have features in common and claim similar routes, and I will but very briefly review them.

The Beach Pneumatic was merged into the Broadway Underground, and this in turn into the New York Arcade Railway Company, and it is now familiarly known as the Arcade. They propose to run from the Battery, thence to Broadway and Madison-square, with four tracks, the two centre being express tracks, with stations one mile apart, and the two outer tracks for way traffic. Thence the route extends to Fifty-ninth-street, by Broadway, and to the Harlem River by Madison-avenue, with an additional route up the west side of Central Park by the Boulevard, or some other avenue, and into the annexed districts. Branches are proposed to connect Broadway and Madison-avenue on Twenty-third-street, and the two branch roads on Forty-second-street.

The Underground Railway Construction Company has pooled the issues of the New York District, New York Underground, and the Metropolitan Junction Company. The route of the first is similar to that of the Arcade, and runs from the Battery to Broadway and Madison-square with four tracks; thence up Broadway to Fifty-ninth-street, and up Madison-avenue, over the Harlem River to some point near Jerome Park. Branches are also proposed from river to river on Twelfth and Twenty-third streets. The New York Underground road proposes to run from the City Hall Park east to Broadway, through Centre and Mulberry streets to Lafayette-place and Fourth-avenue at Union-square. Thence by two lines to the Grand Central and Broadway and Fifty-ninth-street, up the Boulevard to Kings Bridge, the main line continuing under Madison-avenue to the Harlem River, and by a loop to Kings Bridge.

The Metropolitan Junction Company proposes to connect with the two last-named in the annexed districts, and then run over the Hudson by a bridge at Washington Heights, connecting with a tunnel through the Palisades.

The City Railway Company proposes to begin at South and Whitehall streets, crossing Broadway below Rector, running between Church-street and College-place, Sixth and Seventh avenues to Fifty-ninth-street and the Boulevard. The line would then run up the west side of Central Park, crossing the Harlem River above High Bridge, terminating in New Rochelle. Branches are proposed for the principal ferries on both rivers, the Post Office and Grand Central Station. The roadway is intended to be 50ft. wide and 12ft. below the street surface; it is to have four tracks, two way and two express. It differs from the other underground railways in that instead of taking the street lines it proposes to purchase the necessary property and erect buildings over the line of the road, which are to be rented for sufficient to pay the bonds of the company. The road thus running through the basements, so to speak, of the buildings, and crossing the streets by tunnels, becomes a covered roadway instead of an open one.

The Terminal Underground Railway Company proposes a four-track underground railway from the City Hall along the proposed Elm-street improvement to the Grand Central Depot.

The Metropolitan Transit Company proposes two elevated steel structures, one on Broadway, between Chambers-street and Forty-third-street, connecting with the Grand Central Depot, and the other on the west side, following the line of the water front to Gansevoort Market, thence up Tenth-avenue and the Boulevard to Kingsbridge.

The plant proposed by Heman Clark is one of the most radical. He proposes a four-track tunnel, beginning near Fleetwood Park, cut in solid rock 150ft. below the surface, coming down about 100ft. west of the line of Broadway to the Astor House, where it would connect with two two-track branches, one going under the North River to Jersey City and Newark, and the other under the East River to Brooklyn and Prospect Park. Passenger stations would be at the foot of shafts sunk every two miles, and freight stations at intermediate shafts where freight pockets would be tunneled. Large elevators would be used for handling the passengers and freight.

All of these schemes have their good and bad points which I do not propose to discuss here; but whichever is successful, they hope to use electric motors for propulsion. Now, whatever we may claim for electrical motors, it would be folly to attempt the handling of the traffic of such a road without full knowledge as to the character of the work which has to be performed, and a perfectly definite idea of the system of train dispatching which will best meet the wants of the public, and, at the same time, preserve an effective and economical system of operation. To fully consider this, let us briefly review the work which is being done on the elevated railroads—for example, on the Third Avenue line.

This is eight and a half miles long. Grades vary from eight to 105 feet to the mile. The level stretches amount to about one-third of the whole distance, and this includes the stations. On the 17 miles of single track there are 52 stations. In the busy hours there are no less than 63 four and five-car trains on the tracks. These trains, weighing from 80 to 95 tons, make the half trip in 42 minutes, including stopping at 26 stations, and discharging and taking on passengers, or at the rate of about 10 traffic miles per hour. The work of the engines may be divided into three parts—viz., overcoming the train's inertia, lifting the train on the grades, and traction—and the maximum is at least seven times that necessary for traction at mean speed on a level. Three times in every mile this weight of 80 to 95 tons must be started from a dead rest, raised to a speed of twenty or more miles an hour, and brought to rest in about eighty seconds. The engines have to be run with 130 pounds boiler pressure, and have a capacity of 185 h.p. Fifty-nine per cent. of the power on a round trip is used in starting, 24 per cent. in lifting, and 17 per cent. in traction, and the average power developed per minute per round trip, including stoppages, is 70·3 h.p.

The traction necessary to handle these trains is obtained by a locomotive weighing 22½ tons, of which only fifteen are carried by drivers 5ft. apart. With an engine and the forward trucks of one car between two girders,

Digitized by Google

we have a weight of nearly 1,500 pounds per running foot. The present weight of engines is not sufficient to properly handle these trains when the tracks are in a slippery condition, and it is not wise to increase it. It is absolutely necessary to keep up the high character of the engineering work of this road, and every consideration of business prudence and public safety will permit of no laxity in this direction. Yet these locomotives have done wonderful work. Although on duty for twenty hours, with steam admitted to the cylinder for six hours only, with an average horse-power of only 38 per cent. of the maximum, and with all the incidental losses of steam, they develop a horse-power with less than a total expenditure of 6·2 lb. of coal per hour; and the coal expense alone is only about 1dol. 15c. per round trip, or 2½ cents per train station. The operating expenses are 62 cents per train mile, or allowing an average of four cars per train, 15½ cents per car mile, and this includes everything.

The percentage of expenses of operation and maintenance for the whole Manhattan system may be roughly expressed as follows:

Motive power	42.8
Maintenance of cars	5.4
Movement of traffic	38.4
Maintenance of way	8.2
General expenses	7.2
Total	100.0

The coal alone costs over 700,000dols. per annum, which is more than the wages of the engineers and firemen, but it is only about one-sixth of the total operating expenses. Hence there are other reasons than merely a saving in coal which must be urged in favour of an electric system as against a steam system.

Generally speaking, the real needs of rapid transit are not best subserved by the handling of long trains from a single tractive-engine True, the conditions of service on the elevated railroad, the crowded condition of the track, and the great cost of operating independent steam-engines makes it impracticable to work with small train units there. But the fact remains that the effective length of train which can be operated by any system is limited; that this limit has already been reached on the elevated railroad, where only one-sixth of the weight is now effective for traction; and that the smaller the units the less the momentum of the train, and the easier it is to quickly and efficiently handle it, and the less will be the liability of, and danger from, any derangement of the brake apparatus. Furthermore, the thrust of the moving weights on the grades, the vibration due to the shifting of the weight along the girders, the tensile, shearing, and crushing strains on the structure are all materially increased by the use of a heavy locomotive at the head of a long train.

But since we must endeavour to meet all conditions of engineering, we must try to meet that one which requires the operation of a heavy train by a single-motor car. In this case, I deem it advisable to make the motor car of about the same size as the cars which form the train, equip both trucks, and thus spread the weight used for tractive purposes over a larger distance. We have now partly constructed a 300-h.p. motor equipment of this character.

This car, whose general external dimensions are similar to those of the regular elevated passenger coach, differs in its construction in many important details. The front and rear platforms are enclosed, and about 10ft. at each end of the car—that is, the space over the trucks—is partitioned off and reserved for the use of the motor man. The middle space has side entrances, and is fitted for passenger accommodation. At each end of the car the floor-framing is raised about 12in. for a distance of about 10ft. from the end, and the car body is carried on two very strong and heavy special iron trucks mounted on 42in. wheels fitted with 5in. steel axles. Each axle has an independent movement, and is driven by a tandem motor, centred upon the axle, which bears a part of the weight. The motor is also carried by heavy compression springs hung from the truck, by means of which as much of the weight of the motor as is desired can be thrown on to the boxes. Each motor, which is of about 75 h.p. normal capacity, has two armatures, each of which is connected to a fixed and adjustable gear on the axle, the ratio of the gearing being about one to three. These motors will have one brush on each commutator, and that will be a top brush. Each motor has directly over it, in the engineer's room, trap doors fitted with heavy glass panels, which allow the machines to be seen at all times, and through which the machines can always be reached. The controlling devices and switches are all duplicates, and the car can be handled from either end. The car and the trucks are completed; the motors are well under way. The car will be capable of exerting a tractive strain of at least 20,000 lb.—more than double that of the present locomotives.

But this is not the ideal method of traction.

By a system of electrical propulsion, the power can be distributed underneath the cars, every car, or every two if need be, being a unit; and, although I do not think it advisable, arrangements could be made for propelling a large number of cars under simultaneous control. By distributing the power under the car, the whole weight of the car and passengers can be made effective for traction. This will enable the cars to be started more promptly, brought to speed more quickly, and stopped in shorter intervals increasing the mean rate of speed for a given maximum, or *vice versâ*, reducing the maximum for a given mean rate. By making cars individual units of locomotion, the intervals between trains may be made one-fourth or one-fifth of the schedule which must exist where four or five-car trains are used. It may be said that this will increase the number of employés that are necessary. This is true, but it will increase the number of passengers who, both day and night, would make use of the system in such a ratio as would make this increase of expense insignificant.

Let us consider a possible system which would go a long way towards solving the question of rapid transit. I will briefly point out its features. It would have four tracks, extending from the Battery up Broadway to Twenty-third-street, thence diverging in two divisions, each still with four tracks, one along the line of Madison-avenue to the Harlem River, and terminating near the Jerome Park district, the other following Broadway, and running up the line of the Boulevard and Tenth or Eleventh avenues. Two tracks would be reserved for express traffic, with stations a mile apart, and two for way traffic, with stations every third of a mile, and every third way station corresponding with an express station. The tracks would be arranged in two tiers, the express tracks being the lower. The entire system would be lighted, ventilated, and operated by electricity, to be supplied from four stations on the water front—one at the Battery, one at East Twenty-third-street, one at Madison-avenue crossing of the Harlem River, and one on West One Hundred and Twenty-fifth-street; the stations to be operated by compound condensing engines in three units, connecting directly to large, slow moving multipolar dynamos, two engines being of sufficient capacity to handle the demand made upon any station; trains to be operated with one, or at most two car units; motors to be on the trucks of one car, centred on the axle, and with one reduction of gearing, express speed to be 30 miles an hour, and way trains to make 12 traffic miles per hour; the current to be delivered to the cars by an overhead system with underneath contact, the contact wheel to be carried on the car, supported over the centre of the truck and trending a little abaft it. Freight pockets at the level of the way track could be run under the cross streets at express stations. Track to follow a line of grade of not more than 25 per cent.; access to stations to be by stairways, and where there is any material difference between the street level and the track, by hydraulic elevators, operated from constant pressure tanks kept supplied automatically by electric motors. Freight trains to be run on way tracks.

Supplementing this system should be a line of surface cars, likewise operated by electricity from the same general source. In the heart of the city these can be operated from a conduit, or by the storage battery, and in all the suburban extensions by the overhead line system.

The objection of loss in transmission and recovery has been raised as against an electric system, and also the question of breaking. These are easily met.

We have systems of electrically breaking a train by the use of its motors, which consists in converting them into dynamos, deriving their driving power from the train, and

Digitized by Google

using up its energy by converting it into electrical energy, which can be used in a variety of ways. In a storage battery system the energy of the car can be made to partially recharge the batteries on a down grade, and in stopping. In a direct supply multiple-arc system, operating a large number of cars, this power of being able—at will — to convert the energy of a moving train into electrical energy delivered to the line by the same apparatus which controls the speed and power of the train is of exceptional importance. In a double track system the energy given to one track may be communicated to the other just as efficiently as along itself. In fact, in the entire electrical system every part is mutually connected, and there is a bond of union between the different trains far more perfect and effective than any mechanical connection could be. The up-grades on one track being equal to the down-grades of the other, it is evident that the total up-grade of a system is equalised by the down-grade thereof. If, then, energy is expended in getting under way and climbing up-grades, and a large proportion of this can be recovered in stopping and in running down grade, it is evident that the total initial energy required would be that necessary to remove the trains continuously on level grades, with a percentage for loss in conversion and reconversion added. The more train units which are operated, and the more frequent the stoppages, the more marked is this advantage in an electric system.

I some time since made a number of determinations of a system of the equipment capacity of the Third-avenue Elevated, in which I found that about 40 per cent. of the power could be saved by this system of breaking, where every motor coming to a station or running on a down grade is made a generator which is helping to supply the current needed to operate the remaining trains.

Instead of the current being all supplied by a main generating station at one or two points, it would be supplied from nearly as many moving stations along the line as there would be trains slowing down or running on a down grade. In fact, the loss of the two conversions and one transmission would be more than counterbalanced, and consequently the original h.p. at the central station would be no more than the aggregate net h.p. now developed on the entire line, and this is only about 38 per cent. of the total capacity of the engines. With any given potential and losses on the line, the main conductor would be very much smaller. Not only on the line, but at the central station would be a saving effected; for in a system of the capacity of that which we are considering this saving on lots, buildings, boilers, engines, dynamos and fittings would be not less than 400,000dols., and there would be about 40 per cent. saving in the coal, labour, depreciation, and incidental expenses of the central station.

Another method of using the motors for braking purposes is to break the connection from the line and reverse the machine through a local circuit on the train, varying either the local circuit or the circuits of the machine. While in this position of braking, if the local circuit is opened and the line connection made, the machine would be instantly reversed.

Elaborate experiments were made by me nearly two years ago on the Thirty-fourth-street branch of the New York Elevated Railroad, in which these questions of gearing, of mounting the motors on trucks under the car and handling the car without shoe-brakes were very thoroughly studied. There this method of braking was shown to be under the most perfect control. When desired, the braking could be made so sudden as to cause the wheels to have a continuous skidding rotation, not such a skidding as is caused when an air brake is put on too sharply, but a rotating slip, which is just enough to relieve the armature when the strain on it reaches the point determined by the co-efficient of adhesion on the rails.

This is the ideal method of braking, because fixed skidding and flat wheels are an impossibility, and the wheels will turn until the train comes to a dead stop, although, where the breaking power is put on too suddenly and exceeds the grip of the wheels, they will relieve themselves by slipping just enough to keep the braking at the maximum limit. A train so governed can be made to creep down the maximum grade of a road at a snail's pace, and in an emergency such a car, running at 21 miles an hour on a down grade, has been stopped and reversed within 90ft.

When an electric motor is reversed its action is cumulative, for so long as its motion continues in its normal direction, it tends to augment the current which flows through it with any given setting of the switch, and thus very much increases the effort to stop itself; and the higher the velocity at which the armature is travelling, the greater this effort. In fact, it would be practically impossible with a properly constructed railroad motor to prevent its reversing when the switch is thrown over far enough. This is another point in which an electric motor has a great advantage over a steam engine.

So it would seem that electricity has practical advantages over steam for this character of traffic, and there are considerations other than purely engineering ones. The use of electricity instead of steam would do much towards making a road of this character popular. We would have express and way trains, starting and stopping smoothly and quickly, moving at a high rate of speed and running at short intervals. Dust, smoke, cinders, oil and drippings would disappear; the air would be purer and cleaner. The trains would be safer and under more perfect control; motive power would cost less; depreciation on the track structure would be much less; the carrying capacity would be increased; cars would be brilliantly lighted, comfortably heated; in short, everything which would make rapid transit safe, pleasant and effective is possible by a properly developed system of electric traction.

One of the most important sources of revenue from such a system would be the sale of power for stationary purposes. Already we are operating no less than 130 different industries by electric motors, and the receipts vary from 60 to 150dols. per h.p. The extent of the application of electricity with any such general source of supply can hardly be conceived. Its profits would be far more than enough to pay the total cost of motive power.

But we must not shut our eyes to the work which has got to be done. We must not exaggerate the advantages of electricity; we must not belittle the position of a system which has been developed by the ablest engineers for the last forty years. All their experience, all their study, all their victories, form a magnificent groundwork for us to build upon, and will render the final victory of electricity more easy and certain if we build wisely and take to heart all the lessons which their years of experience teach us. In a small fraction of the forty years which have marked the development of steam engineering, electric engines will rival in mechanical perfection, in construction, and performance the best locomotives. Even to-day, weight for weight, and duty for duty, the electric motor is already rivaling and outstripping its predecessor. For the present, and for a long time to come, it is probable that for trunk-line work and for the original source of our power in an electrical system, we will be dependent upon the steam-engine, but we all hope and expect that the future will bring us some other effective means of converting the energy of coal into electrical energy, and that by some direct method which will not require the intervention of a steam engine and dynamo. It is not too much to hope for, and already experiments have been made which foreshadow this great result. The success of this discovery would produce such a revolution in the use and distribution of power as to exceed our most sanguine expectations.

SPECIFICATION OF WIRING.*

By the term wiring, is meant the whole of the materials and work for a thoroughly perfect electric installation of incandescent lamps erected and fitted up complete, in or upon the buildings in the occupancy of Messrs. Hampton and Sons, namely, Nos. 8, 9, 10, Pall Mall East, Nos. 1 and 2, Whitcombe-street, and the building in Monmouth-court, London, S.W., with the following exceptions only, namely, no electrical or other machinery, or any apparatus for generating or storing electricity, or any converter, or work in connection therewith is included.

The whole of the buildings are to be lighted throughout. There

* Proposed electrical installation in the buildings occupied by Messrs. Hampton and Sons, Pall Mall East, Whitcombe-street, and Monmouth-court, London, S.W.

Digitized by Google

must be no interference with the existing gas lighting without permission.

The tender must be in four separate portions, as set forth in the accompanying schedule.

The parties tendering must supply a schedule and plan describing the manner in which they propose to light each shop, show-room, office, passage, corridor, staircase, or other part of each building. The number of lights must be stated, their individual candle-power, how arranged, what fittings it is proposed to supply, and their make and design. The method of arranging the conductors, and full details of how they propose to place up the whole installation.

No existing chandeliers or gas-fittings are to be utilised.

There are to be no combination fittings.

The tender must be for a thoroughly complete and perfect installation for each building, down to the smallest details. It must include the cost of all cutting and making good again, and the contractor is to provide all necessary implements, scaffolding, and apparatus, and a sufficient number of skilled workmen and labourers for the proper, expeditious, and complete execution of the works and cleaning up and removal of waste materials. And he is to supply any workmanship, materials, and labour which, although not specially named in this specification, may be, nevertheless, incidentally necessary for the proper and expeditious completion of the work described therein. And the contractor is to make good again at his own cost any damage or destruction that may occur to the works, whether by accident or any other cause whatsoever, until the installation is completed.

The contractor is also to be responsible for any damage or injury done to the buildings or to the property belonging to Messrs. Hampton and Sons that may be occasioned by the act of any of those in his employment (any property held in trust is to be considered for this purpose as the property of Messrs. Hampton and Sons).

The business carried on in the premises is not to be interfered with in any way during the progress of the work. No work is to be commenced after 10 a.m. or carried on before 6 p.m. without permission in writing.

All materials and work are to be of the very highest character and excellence.

The contractor must keep the entire installation in thorough working order and repair, at his own expense, for a period of 12 calendar months from its completion, renewal of worn-out lamps excepted.

No extra, additional, or different work will be allowed for under any circumstances whatsoever, unless an order for the same be given and signed by Mr. Musgrave Heaphy (acting for Messrs. Hampton and Sons) specifying that it is for extra or altered work.

Should Messrs. Hampton and Sons (or their representative) desire the position of any light or lights to be altered from what had previously been arranged, either before or during the progress of the work, this is to be done without any extra charge, provided it does not necessitate any work that has been placed up being done over again.

All work and materials and the entire installation in each building are to be subjected to the approval of Mr. Heaphy (acting as aforesaid), and he is to have the power of rejecting any work or materials he is not perfectly satisfied with.

All insulation tests must be to his complete satisfaction. They must be extremely high, especially with regard to earth.

If, however, from hidden or from any other causes whatsoever, within the said period of twelve calendar months, it be found that the installation, or any part of it, in any of the buildings is not working efficiently, then it shall be in the power of Mr. Heaphy to refuse to pass such part or the whole of the aforesaid installation until it has been altered and arranged to work efficiently and to his entire satisfaction, and this notwithstanding that the materials, work, and arrangement had previously met with his sanction and approval.

The whole of the work of each tender must be finished within the time specified in schedule for each portion of the work after the order to proceed with the work has been given, under a penalty of two guineas per day, for each day after that date the installation is incomplete, unless a certificate be given by Mr. Heaphy stating that such delay arose from circumstances reasonably beyond the control of the contractor.

If, in the judgment of Mr. Heaphy, the work is improperly conducted or sufficient despatch is not used about it, Messrs. Hampton and Sons shall have the power, upon giving to or leaving at the last-known place of residence or business of the contractor six days' notice in writing to dismiss him and his workmen from the works either wholly or in part, and to appoint other persons, contractors, workmen or labourers, who shall supply either by day-work or otherwise the requisite labour, workmanship, materials, means, and appliances for the due execution and completion of the contract; and the costs and charges incurred by them, or any of them, in so doing shall be ascertained by Messrs. Hampton and Sons, and paid for or allowed to Messrs. Hampton and Sons, by the contractor; and it shall be competent for Messrs. Hampton and Sons to deduct the amount of such costs and charges out of any money due, or to become due, from them to the contractor.

Payment on account of 80 per cent. of the contract price will be paid within one week of receiving a certificate from Mr. Heaphy that the whole of the work is complete and to his satisfaction, the balance will be paid at the end of 12 calendar months; provided the installation is then in a thoroughly good and efficient condition free from any defects arising from any bad workmanship, materials, or from any other cause whatsoever.

In the event of any lawsuit or injunction being brought against Messrs. Hampton and Sons, for using any part or parts of the installation placed up by the contractor, then the contractor shall indemnify Messrs. Hampton and Sons for any loss or expense they may have been put to in the matter, that is to say, if such lawsuit or injunction arises out of alleged infringement of patents only.

The lamps to be used must be Edison-Swan of 100 volts, and 16 or 18 c.p. (nominal) each.

No lamps are to be considered as less than 16 c.p. (nominal) each, so far as the conductors are concerned.

The lamps must be arranged in simple parallel.

The lighting of the show-rooms and windows must be *brilliant*.

The lights in the various buildings are to be all single, either suspended from the ceilings or fixtures on the cornices, walls, or other portions of the buildings, as may be determined upon by Messrs. Hampton and Sons.

The position of all lights must be such as meets the approval of Messrs. Hampton and Sons.

Should Messrs. Hampton and Sons, or their representative, desire the position of any light, or lights, to be altered from what had previously been arranged, either before or during the progress of the work, this is to be done without any extra charge, provided it does not necessitate any work that has been placed up being done over again.

The arrangement of the wiring, wherever practicable, must be as follows:—

The conductors from the converters must be brought to main switch-board in the converter house (or other position that may be determined). From this switch-board main circuits are to come into the buildings and be brought to distributing switch-boards, and there split up into small branch circuits, carrying not more than five amperes. Where a main circuit cannot conveniently be brought to a distributing switch-board, then it must be divided up into sub-mains, or branches, which must be so brought to distributing switch-boards.

The number of main circuits proposed must be stated in the tender.

The wiring must be so arranged that no show-room will be dependent upon one main circuit.

All work *must be surface*, except where permission to the contrary from Mr. Heaphy is given. In the event of any work being placed between floors and ceilings, special precautions against fire, as directed by Mr. Heaphy, must be taken.

The switch-boards must be of an approved incombustible and non-conducting material (if slate be used care must be taken that it is of a non-conducting quality). The switch-boards must be furnished with a switch and cut-out for every conductor.

The distributing switch-boards must be mounted on oak or teak, and have glass cases furnished with lock and keys all to pass.

The utmost care must be taken with regard to the design and arrangement of all work in connection with them, and drawings must accompany the tenders. The tenders must also state the number it is proposed to place in their positions, and the number of circuits it is proposed to lead from each.

The wiring must be so arranged that it will be equally suitable to be utilised whether the electricity be generated on the premises or supplied from the London Electric Supply Corporation by their system of high tension primary currents and converters (the E.M.F. of the secondary current being 100 volts), or from any other source. No portion of the primary work is to be included in the tender, but the tender is to include the cables from the main switch-board to the converters, the positions for which will be pointed out on the spot.

The arrangement of the wiring must be such that lamps of the same nominal candle-power will be equally brilliant in all parts of the buildings mentioned in the schedule when the electricity is on. The whole responsibility of this must rest on the contractor.

The contractor must also produce a certificate from the London Electric Supply Corporation, stating that the installation is thoroughly suitable and efficient so far as their system is concerned. This certificate must be produced before any payment will be made to the contractor.

All conductors must be composed of copper of at least 98 per cent. conductivity.

All conductors must be composed of strands.

No conductor is to be of less size than the equivalent of No. 18 B.W.G., unless permission is given.

All conductors are to be insulated in the highest manner with very thick indiarubber of the best quality, and they are to have substantial coverings of braided hemp. Samples of the kind and quality required can be seen.

No conductor is to carry more current than 150 amperes.

No conductor is to carry more current than the proportion of 500 amperes per square inch of section in the case of the mains and principal branches; nor more than the proportion of 750 amperes per square inch of section in the case of the smaller branches or wires.

No twin wires are to be used, except in those cases where permission has first been given. They must be of special make.

The conductors in the converter-room must be bedded in the walls (well apart) or placed in fireproof casings as may be determined by Mr. Musgrave Heaphy.

The position of all conductors must be indicated by a distinguishing mark in those instances where the conductors are hidden out of sight.

There is to be no bunching at the positives together, or the negatives together, without permission.

All conductors are to be encased in substantial, hard, well-seasoned wood casing. The positives and negatives must be placed in separate grooves, and where required filled in with silicate cotton, or asbestos, or other approved putty. The width of wood between the grooves should not be less than two inches in the case of the mains, one inch in that of the principal branches, and three-quarter inch in that of the smallest branches.

The covers of the wood casing should be screwed on, and the width of the sides of the casing should be amply sufficient to allow of screws being driven in when required.

All wood casing must be treated with an approved fireproof paint or compound. Reference must be made to Mr. Heaphy as to the treatment the wood casing should receive, and the paint or compound to be used. The casing should be composed of the wood known as "American white wood."

All wood casing where required to be of such ornamental character as to meet the approval of Messrs. Hampton and Sons,

Digitized by Google

All joints must be thoroughly well made and soldered, and must carefully insulated. Specimens showing how the joints are to be made and insulated can be seen.

Cut-outs are to be placed upon all conductors down to the very smallest. Every change of section must be protected by its own separate cut-out. Single cut-outs may be used for single lights, except where they are taken directly off a main, or main branch, in which case a cut-out must be placed on each conductor.

All cut-outs must be in incombustible boxes, and none are to be placed under floors, or otherwise hidden out of sight except in those instances in which special permission is given to the contrary.

The connections of the cut-outs should be soldered where practicable.

All cut-outs must meet the approval of Mr. Musgrave Heaphy, to whom samples must be sent before any work is commenced, and who should be consulted on the matter previous to the tenders being sent in.

All lamp-holders must be of an approved type, and as incombustible as possible.

All switches must be of the best possible make and design, and such that they will not be able to rest in any intermediate position between full on and off. Samples must accompany the tender.

All switches must be mounted on slate or other approved incombustible material, and when not on the switch-boards must have behind the slate an oak or teak backing.

In many cases, individual lights must have switches. These may be single-pole.

A sketch must accompany the tender, showing how the whole of the work is to be arranged.

A sketch, showing the make and design of each fitting it is proposed to supply, must accompany the tender.

All work in connection with these must be of a specially secure character.

All ceiling roses used must be of a specially secure character, and samples must accompany the tender.

The tender must state the character of the shades it is intended to supply. Samples must be sent.

Sufficient incandescent lamps for each portion of the whole installation, together with 50 extra ones, are to be supplied.

After the work is completed, one copy of plans, properly drawn, coloured, and framed and glazed, showing the position of the work in every portion of the buildings must be supplied by the contractor free of cost.

The position of all work, down to the smallest detail, must be such as meets the approval of Mr. Heaphy, and no work is to be commenced in any portion of the building without previous consultation with him and with his permission.

The greatest possible care must be taken that the decorations in the rooms, passages, corridors, and other portions of the buildings are not injured, and that the work, as much as possible, harmonises with them.

With regard to fire risk the whole of the work must comply with the Phœnix Fire Office Rules (thirteenth edition), and must be to the satisfaction of Mr. Musgrave Heaphy, and his approval must be obtained before any payment will be made to the contractor. It would be preferable if he were consulted before any tender was sent in.

In the event of any dispute or question arising between the contractor and Messrs. Hampton and Sons (or their representative) on any matter whatsoever connected with the work or the interpretation or meaning of any part or the whole of this specification at any time during the progress of the work or after the work has been completed, or after the before-mentioned twelve months has expired, then such question or dispute shall be referred to Mr. Musgrave Heaphy to arbitrate upon and decide, and his decision shall be accepted as final and conclusive on both parties.

A schedule of prices for any extra lights (including portable lights) or work that may be required must accompany the tender. A separate sum must also be stated with regard to the cutting away and making good again, and also for the wood casing (not fixed up).

Messrs. Hampton and Sons do not bind themselves to accept the lowest or any tender. They may accept any one or more of the four portions of the tender to the exclusion of the rest. The parties tendering must do so at their own expense.

A separate tender may be sent in, stating at what price per annum the whole installation would be kept in thorough working order, and repair after the expiration of twelve months mentioned in this specification.

CITY NOTES.

Monte Video Telephone Company.—Letters of allotment in the Monte Video Telephone Company, Limited, have been posted.

The Bernstein Company.—The Bernstein Electric Lamp Company notifies that their offices will in future be at 2, Marlborough Mansions, Victoria-street, S.W.

Brazilian Submarine Telegraph Company.—The traffic receipts of the Brazilian Submarine Telegraph Company, Limited, for the week ended August 10, 1888, amounted to £4,944.

Eastern Telegraph Company.—The Eastern Telegraph Company, Limited, notifies the interruption of its Aden-Bombay cables. The repairing ship will be in the locality of the fault in a few days' time.

Western and Brazilian Telegraph Company. — The traffic receipts of the Western and Brazilian Company for the past week, after deducting the "fifth" of the gross receipts payable to the London Platino Brazilian Company, were £4,141.

Telephonic Apparatus.—Mr. Justice Kay has made an order for judgment for the plaintiffs in an action brought by the United Telephone Company against W. D. Berry and Sons, of Huddersfield, scientific apparatus makers, for alleged infringements of telephonic apparatus.

London-Platino Brazilian Company. — This Company notifies that the half-yearly coupons, which fall due on September 1, 1888, of its £100,000 six per cent. debentures, will be paid by Messrs. Glynn, Mills, Currie, and Co., of 67, Lombard-street, London, E.C., on and after that date; and also that coupons must be left with the bankers three clear days for examination.

NEW COMPANIES REGISTERED.

The Electrical Accumulator Association, Limited.—Registered by Parker, Garrett and Parker, St. Nicholas Rectory, Cornhill, E.C., with a capital of £10,000 in shares of £10 each. Object: To purchase and acquire, and work and use the letters patent for the United Kingdom, No. 8,379 of 1886, granted to Anthony Reckenzaum, entitled "Improvements in Secondary Batteries or Electrical Accumulators," or any interest therein; to manufacture and provide, sell, deal in, or let for hire or grant licenses for the use of any instruments, machinery or apparatus for accumulating, storage, regulating, or measuring the supply of electricity or electrical currents in force. The first subscribers are:

	Shares.
A. Reckenzaum, 7, Albert-terrace, Clapham	1
J. Stephen, 1, Cuba-street, Millwall, E.	1
W. Adams, Hithersett Lodge, Putney, S.W.	1
J. R. Anderson, Stretton House, Putney	1
R. Grant, Faruleigh, Westgate-on-Sea	1
A. Smith, 1, Cuba-street, Millwall, E.	1
G. Binswanger	1

The company is registered without articles of association.

The Lineff Electric Traction and Lighting Syndicate, Limited. Registered by Shaen, Roscoe, Massey and Co., 8, Bedford-row, W.C. Capital, £10,000, divided into 10,000 shares of £1 each. Object: To acquire, introduce, work, develop, and manage certain new inventions for operating tramways or railways by means of electricity, for which letters patent have been granted, one of which bears date June 10, 1887, and is numbered 8,380, and the other of which bears date October 4, 1887, and is numbered 13,447, and all the benefits, privileges, and advantages of, or to be derived from, the said inventions and letters patent, and to take out or acquire letters patent for the said inventions in any colony or foreign country; to light roads, thoroughfares, houses, shops, or public buildings. The first subscribers are:—

	Shares.
R. Applegarth, 11, Queen Victoria-street, E.C.	1
A. G. Lineff, 88, High-road, Chiswick	1
E. H. Bayley, 42, Newington-causeway, S.W.	1
R. G. Applegarth, 11, Queen Victoria-street, E.C.	1
A. E. Stone, 11, Queen Victoria-street, E.C.	1
E. G. Church, 120, Pollock-road, New Kent-road	1
J. S. Keay, 90, Ladbroke-grove, W.	1

There shall not be more than five Directors, and the first shall be E. H. Bayley, J. S. Reay, A. G. Lineff, and R. Applegarth. Each Director shall hold at least 250 shares in the Company. The remuneration to the Directors shall be fixed by the Company in general meeting.

Laurence, Paris, and Scott, Limited.—Registered by F. G. Monkland, 78, Gracechurch-street, E.C., with a capital of £30,000, in shares of £10 each. Object: To adopt and carry into effect an agreement dated June 24, 1888, and made between E. A. Paris and W. H. Scott of the first part, R. Laurence of the second part, and G. Cruikshank, as trustee of the Company, of the third part; to acquire and carry on the business of E. A. Paris and W. H. Scott, electrical engineers. The first subscribers are:—

	Shares.
E. A. Paris, King-street, Norwich	1
A. J. Laurence, 13, Copthall-court, E.C.	1
W. H. Scott, King-street, Norwich	1
R. Halewood, Norwich	1
T. W. G. Taylor, Norwich	1
P. E. Laurence, 13, Copthall-court, E.C.	1
L. Laurence, Clapham-park	1

The number of Directors shall not be less than three nor more than eight, and the first shall be R. Laurence, E. A. Paris, and W. H. Scott. The qualification of a Director shall be the holding in his own right of at least 100 shares in the capital of the Company. The remuneration of the first Directors shall be the sum of £250 per annum each, and 25 per cent. of all net profits after 5 per cent. per annum dividends have been paid.

PROVISIONAL PATENTS, 1888.

AUGUST 3.

11,274. **Improvements in galvanic belts or chains.** John Beveridge Thistleton, 53, Chancery-lane, London.

AUGUST 4.

11,312. **Certain improvements in scoring boards used by billiard players and others, and in means for operating the indicating devices by electricity.** Joseph Hamer, Commercial-street, Halifax.

Digitized by Google

11,328. **Improvements in obtaining electricity for electric lighting motive power and other like purposes.** William Boggett, 34, Southampton-buildings, London, W.C.

11,338. **Improvements in telephone line circuits.** Leon Kelner, 24, Southampton-buildings, London, W.C. (Complete specification.)

AUGUST 7.

11,352. **An improved electric pen or pen and holder, specially applicable for stippling and similar purposes.** Joseph Scholefield, 2, East-parade, Leeds, Yorkshire.

11,354. **New or improved methods of and apparatus for utilising energy and the application thereof to a certain useful purpose.** James Grieve Lorrain, Norfolk House, Victoria Embankment, London, W.C.

11,376. **Improvements in syphon recorder telegraph instruments.** George Draper and William Henry Ash, 50, Old Broad-street, London, E.C.

11,377. **Improvements in syphon recorder telegraph instruments.** George Draper and William Tuck, 50, Old-street, London, E.C.

11,388. **A system of, and means or apparatus for, automatically and electrically indicating the breaking of a train, or for actuating signals on railways.** John Leman Eckersley Daniel, 68, Fleet-street, London.

11,403. **Improvements in apparatus for the propulsion of vehicles by electricity.** Henry Harris Lake, 45, Southampton-buildings, London. (Francis Joseph Weis, United States.) (Complete specification.)

11,411. **Improvements in armatures for dynamo-electric machines.** Alexander William Meston, 77, Chancery-lane, London, W.C. (Complete specification.)

AUGUST 9.

11,475. **An improved electrical stop-motion for automatically arresting the operations of apparatus for folding envelopes and similar articles of paper.** Carl Blanke, 1, St. James'-square, Manchester.

11,479. **Improvements in the manufacture of iodine and iodoform by electrolysis.** Thomas Parker and Alfred Edward Robinson, 70, Market-street, Manchester.

11,490. **Improvements in lock switches for electric circuits.** Arthur Cecil Cockburn, 2, Aubert-park, Highbury, London, N.

11,491. **Improvements in the insulation of electric conductors and for the preparation of wires to prevent vibratory sound when used for telephonic and other electrical purposes.** Donald Nicoll, 12, Buckingham-street, Charing Cross, London, W.C.

11,495. **Improvements in the arrangement and construction of telephonic exchange systems.** John James Mann and James Cutlan, Ordsall Lane Mills, Salford.

11,503. **Improvements in electric generators.** Lazarus Simon Magnus Pyke and Harry Theodore Barnett, 433, Strand, London.

11,511. **An improved system of automatic electric signalling for railways, and means or apparatus for use therewith.** John Leman Eckersley Daniel, 68, Fleet-street, London.

11,514. **Electrically controlled apparatus for checking, extinguishing, and preventing the spread of fire, and for simultaneously giving the alarm.** Thomas Ralph Douse, 166, Fleet-street, London.

COMPLETE SPECIFICATIONS ACCEPTED.

AUGUST 2, 1887.

10,611. **Improvements in electrical batteries.** Richard Philip Milburn, 46, Grainger-street West, Newcastle-upon-Tyne.

AUGUST 6, 1887.

10,833. **Improvements relating to electric lamps.** Frederick Richard Boardman, 433, Strand, London.

10,838. **Improvements in electrical switches.** Frederick Lawrence Rawson and William White, 1, Queen Victoria-street, London, E.C.

AUGUST 10, 1887.

10,952. **Improvements in or connected with dynamo-electric machines and electro-motors.** Lucien Anspach and Léon Gerard, 433, Strand, London.

AUGUST 31, 1887.

11,802. **Improvements in and relating to the manufacture of incandescent lamps, and the methods adopted for converting old lamps into new, materials used therefor and in combination therewith.** Arthur Shippey, 13 and 14, King-street, Cheapside, London.

SEPTEMBER 9, 1887.

12,203. **Improvements in dynamo-electric machines.** Thomas Lynch Hemming, Cobden Buildings, Corporation-street, Birmingham.

OCTOBER 1, 1887.

13,320. **Improvements in electric regulators.** John Grice Statter and Sidney Linton Brunton, Norfolk House, Norfolk-street, London, W.C.

OCTOBER 6, 1887.

13,558. **Improvements in or relating to casings for electrical conductors and apparatus.** Percival Everitt and Percy Ruskin Allen, 4, South-street, Finsbury, London.

13,567. **Improved automatic electrical firing mechanism for naval ordnance.** Alexander Melville Clark, 53, Chancery-lane, London. (Paul Oriolle, France.)

OCTOBER 15, 1887.

14,024. **Improvements in secondary batteries or electrical accumulators.** Nicholas de Benardos, 47, Lincoln's-inn-fields, London, W.C.

14,029. **Improvements in electrical tramways and railways.** Frederick Charles Allsop, Bexley, Kent.

APRIL 17, 1888.

5681. **Improvements in switches used for electrical purposes.** Charles Scott Snell, Culver Park, Saltash, Cornwall.

SPECIFICATIONS PUBLISHED.

1887.

12,111. **Electric fuses for mines.** W. P. Thompson. (Dumas.) 8d.

12,325. **Telephonic apparatus.** W. Fairweather. (Western Electric Co.) 8d.

12,432. **Motor Engines.** W. D. and S. Priestman. 8d.

1888.

7805. **Producing, &c., electric currents.** H. J. Allison. (Fritts.) 11d.

8223. **Magnetic separator for extracting ferruginous matter from ores, &c.** A. H. Reed. (Conkling.) 6d.

8596. **Automatic telegraphy.** J. Y. Johnson. (Mallet.) 1s. 1d.

NOTES.

Moscow.—Messrs. Siemens and Halske have commenced the work of a central station, which will be situated near the centre of the town.

Cardiff.—The Cardiff Corporation last week passed a resolution to invite the British Association to hold its annual meeting at Cardiff in 1889.

Iron Telegraph Poles.—We learn that Messrs. Bayliss, Jones, and Bayliss, Victoria Works, Wolverhampton, have booked a large order for tubular telegraph poles.

Cruto Lamps.—It is stated that the French patents for these lamps have been obtained by the house of Rothschild for a new company whose factory is situated in Paris.

The Volta Prize.—This prize of 50,000f. has been awarded to M. Zenobe Gramme, for his improvements in dynamo machines. The last award was to Graham Bell for his work in telephony.

Cable News.—It is stated that the French Minister of Finance has submitted to his colleagues a project for a convention relative to the Antilles cable, which it is proposed to submit to the Chamber.

Cost of Maintenance.—The total expense of maintenance, including everything, on a recently equipped overhead electric road running twenty cars, is certified as being only 47 per cent. of the total receipts.

Telegraph Facilities.—The Post Office authorities are erecting wires to give direct communication between Aberdeen and Kirkwall, while otherwise improving improving telegraphic facilities in the North.

Brussels and Paris.—In the exhibition at Brussels opportunity is given of experiencing long distance telephony. The grounds of the exhibition are now connected to Paris, and forty telephones are at the service of visitors.

Who Pays?—During a severe thunderstorm at Wabash, Ind., recently, lightning struck the electric wires and burned out more than half the lamps. The plant had just been accepted from the Heisler Electric Light Company. The damage was repaired in a few days.

An Alternative.—A lineman in New York, in complaining of the bad state of the wires, says: "The only way to find out if the wires are dead or alive seems to be to feel them. If you don't receive a shock the wire is dead; if you do receive a shock, very likely you are dead."

Wire-Covering Machines.—Messrs. Edes and Bradford, of Plymouth, Massachusetts, run their wire-covering machines by electricity. The machines used are invented by the firm, and some of them are so delicate as to cover wires of one nine-thousandth of an inch in diameter.

Innsbruck.—The gas company of Innsbruck are about to establish a central station for the supply at first of about 3,000 incandescent lamps. Water power is to be employed as the prime motor to drive the dynamo, and overhead wires will be used with Zipernowsky transformers. The work is to be carried out by Messrs. Ganz, of Buda-Pest.

Glasgow.—The ship "Marathon," named by Princess Beatrice during the Queen's visit to Glasgow, is one of the new fast-speed vessels expected to get a speed of at least 20 knots on trial. The vessel will be lighted throughout by electricity, and carries three search-lights—one on the conning tower, and two aft on the upper-deck sponsons.

Conduction through Gases.—Nahrwold concludes, from his experiments, that it is impossible to give an electrostatic charge to a mass of gas, but he has not arrived at definite conclusions as to the possibility of separate molecules becoming charged, which, he says, is quite possible, as the charge of the molecules could be dissipated before an observation could be made.

Montlucon.—A company is being formed to establish a central station for lighting this town. Besides lighting, it is intended to distribute current to actuate motors. The charge to be made for an ordinary incandescent lamp will be 60f.—about £2. 8s.—per year. It is thought that this amount is too high, and unless the terms are reduced the enterprise will not succeed.

Edison Plant Burnt.—Edison plants do not seem to be very lucky. Not long ago an Edison central station was burnt out, and great expedition was shown in restarting the station. Now it is the Edison machine shop at Schenectady, containing valuable machinery and apparatus, which were destroyed by fire at the end of last month, with a loss of 32,000dols.

Eastbourne.—The Eastbourne Electric Light Company state they have incurred a serious loss in the contract with the Eastbourne Corporation by supplying 16 lamps on the Grand and Marine Parades, at £25 each per year. They offer to continue the arrangement at £35 each lamp, making a total of £560 yearly under agreement for five years. The Corporation at Hastings pay £30 per annum each lamp.

Railway Work.—It is suggested that it would in some way assist the railway officials, and perhaps the general public, to have an automatic electric annunciator to indicate the time of the departure of trains. We would suggest that for the benefit of the general public it would be far better that each platform be provided with an indicator showing the destination of the next train and the time of its departure.

Leamington.—It will be seen from the report given in another column that the tension which has existed between between the electric light company and the corporation is in a fair way of being satisfactorily settled by mutual concession. The motion to give notice to stop the electric lighting has been by consent withdrawn, and no doubt, if the company and the corporation act together, the whole matter can be soon put upon a satisfactory footing.

Whittingham Asylum.—The whole of the lightning conductor system at the Whittingham County Asylum, Preston, is being extended, and new earth plates inserted to insure a more perfect termination; also twenty new conductors are being erected for the further protection of this expensive establishment. The registered system of Mr. Joseph Blackburn, of Nottingham, has been adopted, and the work is now being carried out by that firm.

The Telautegraph.—The American papers received this week contain illustrated details of Prof. Elisha Gray's new instrument, but the apparatus is not likely to be of any commercial value in this country. The efforts of the Post-Office officials are directed towards rapidity, and the introduction of a writing apparatus of this kind would tend to delay. In private matters and on private lines it possesses few, if any, advantages over the A B C instrument.

Advance Australia.—A Melbourne syndicate has arranged with Messrs. Ganz and Co. to employ, in Australia, the Zipernowsky-Déri-Blathy system. It is stated that a central station is to be erected in Melbourne, where it is expected ultimately the power used will be something like 5,000 h.p. Another is to be installed at Assendon, near Melbourne, where about 500 h.p. will be employed. A third is proposed at Huntershill, near Sydney, which will be about the same size as that at Assendon.

Great Northern Railway.—Messrs. Hammond and Co. have, we understand, received an extensive order from the Great Northern Railway Company to light their new wagon repairing shops and offices at Doncaster. The plant to be supplied consists of three horizontal steam-engines and three dynamos. The lighting will be effected by means of 70 arc and 200 incandescent lamps. Storage batteries will be provided to supply the incandescent light to the offices, as the machinery will not be constantly running.

The Magnetic Field.—We commence in this issue a series of articles which, we do not hesitate to say, will be the most complete and instructive of any that have ever been issued on this subject. In his introductory chapter, Prof. S. Thompson says: "The most important point in theory is the theory of the magnetic field." So far as we are acquainted, the theory of the magnetic field has never been exhaustively treated, and the author of the articles to which we refer proposes to give it this exhaustive treatment.

Chelsea.—At the meeting of the Chelsea Vestry a letter was read from the Chelsea Electricity Supply Company, to the effect that the whole of the capital required for the purpose of supplying the district with electricity, namely, £32,000, had been provided, and that the company would begin the undertaking without delay. The surveyor (Mr. Strachan) said that the company proposed to lay their mains in the streets of the district under Schedule A of the provisional order. It appeared that they had found the money, and were anxious to get on with the work. He had examined the plans, and was prepared to recommend the Vestry to agree to the application. This was agreed to.

Litigation.—Our American namesake, referring to the legal decisions on the Gaulard-Gibbs and the Edison-Swan patents, says: "A careful examination of these cases has but served to confirm our first impression—that the adverse result in both was due to precisely the same cause, viz.: the utter failure of the solicitors (or patent agents) who prepared the specifications to comprehend wherein the real invention consisted, and so to differentiate it properly from the prior work of others. Each ignorantly sought to claim the whole art, instead of the particular step in advance which had really been made, and in thus grasping at a shadow the substance has been permitted to fall to the ground."

Good for Electric Bells.—It is stated that on Wednesday morning last week, at an early hour, an unsuccessful attempt was made by burglars to enter the private residence, Victoria-park-road, of Mr. John Lobb. All the inmates were aroused by the continuous ringing of an electric bell, which the burglars had unwittingly set going. Four policemen were in a few moments on the spot, and although careful search was made for upwards of an hour, the burglars got safely away. As we have often said, it is easy to guard a house electrically, so that no window or door can possibly be opened without warning. It would even be possible to guard against the cutting out of a panel of a door or a large pane of glass from a window.

Technical College Fittings.—Messrs. J. M. Adam and Co., 40, St. Enoch-square, the engineering bureau, Glasgow, have secured the contract for the complete equipment of the new workshop of Allen Glen's Institution from the governors of the Glasgow and West of Scotland Technical College. This will comprise the engine for electric lighting, ventilating, &c., for the whole school buildings, which are being constructed to the designs of Messrs. J. Salmon and Son, I.A.; also the workshop shafting, machine tools, and smithy appliances, and the stock of edge tools, instruments, and general stores for the use of the students. This firm is also engaged fitting up an extensive bleaching and finishing works plant in the Dalmarnock district of Glasgow.

Alternate Currents and Electrolytes.—Two different methods are in use for determing the electrical resistance of liquids, the one by means of constant currents, the other by means of alternating currents. Sheldon, in order to compare the two methods, made a series of measurements by both methods of the resistances of dilute solutions of potassium chloride, sodium chloride, potassium sulphate, and magnesium sulphate, of nine different degrees of concentration. In every case, the results obtained by the two methods were closely concordant, and the author concludes that both the methods, if properly carried out, are capable of giving equally good results, but he decides, according to the *Chemical Society's Journal*, in favour of the alternating current method, on the ground of simplicity and convenience.

Personal.—"On August 15, at the British Consulate, Cadiz, Herbert Laws, younger son of F. C. Webb, Esq., C.E., to Florentine Marie Antoinette (Flora), younger daughter of Joseph Bensusan, Esq., of Cadiz and New York." Such was the announcement in the *Telegraph* of August 16, and many of us who have the pleasure of knowing Mr. Webb hastened to wish him all happiness. Mr. Herbert Webb served the Indiarubber, Gutta-Percha and Telegraph Works Company in the Mediterranean and on the West Coast of South America, where he remained a year in Peru. He was with the Telegraph Construction Company in an expedition in the Red Sea, and has since been four years in the service of the Spanish National Telegraph Company, serving at each island of the Canaries group and at Cadiz, where he has, besides his ordinary duties, placed several installations of telephone, and also at Zerez.

The Liverpool Supply Company.—The new premises of this company, which have been in course of construction in Harrington-street, are practically complete. The machinery, says *Industries*, is duplicated throughout, and is all fixed in position. As soon as all the connections are completed to their existing stations, and to the new system of underground wires, the plant will be placed on duty, and run night and day. An interesting lawsuit, in which this company were the defendants, was decided in the Chancery Court last week. The owner of a hotel near the Tithebarn-street supply station claimed heavy damages for losses incurred by the vibration of the machinery. After scientific and other evidence had been given, the Vice-Chancellor visited the works and the hotel personally, and, after complimenting the company upon the excellence of their machinery and arrangements, gave them a verdict with costs, and refused to stay execution for the latter.

New Book.—We have received the third edition of "Dynamo Electric Machinery," by Prof. Sylvanus Thompson. This edition differs from those which have gone before, and all we have to do at present is to record the publication of this edition, for it has been impossible in the time which has elapsed since the receipt of the book to examine into the changes; but it is easily seen that the first sentence of the preface is correct, and that "most of this treatise has been re-written for this edition, and much new matter has been added. In order to render the work more complete, some historical notes and a brief account of the system of electric units have been added to the introductory chapter. In that part of the book which is descriptive, the machines for furnishing continuous currents have been considered separate from those for furnishing alternate currents. The mathematical parts of the work have been entirely rewritten and curtailed." The work is published by Messrs. E. and F. N. Spon.

Edison and Swan v. Shippey Bros.—We learn that Mr. Arthur Shippey has paid the taxed costs of the Chancery proceedings incurred in this case, and therefore, according to law, the cross action brought by Shippey Bros. against the Edison and Swan Company for intimidation of their customers for using the Shippey lamps, upon which action at the trial, it may be remembered, Mr. Justice Mathews directed a nonsuit pending the appeal, is in its original position, and a fresh suit might be entered upon, taking into account the recent decision of Mr. Justice Kay, and the recent awards granted in favour of the Zanni-Shippey patents on the Continent. It is not unlikely that the Shippey system will be upheld by the owners, who claim the right to manufacture and supply all high candle-power vacuum lamps of 100 c.p. and upwards as specified in the patents; also for the low-resistance composite semi-metallic filaments of the improved King and Harrison types, suitable for battery lighting. The validity of the Shippey patents has not been tried by the English courts.

Gas and Electricity.—The effect of the electric light upon the gas companies is put thus by a New York stockbroker: "The effect has been to increase the use of gas. This is remarkable; but, nevertheless, the facts prove it to be the case. This, and natural growth of the population, has required nearly all the gas companies to increase their plants. The New York Consolidated has, within the last three months, issued for such improvements 700,000dols. 5 per cent. debt certificates (these have been disposed of by the company at over 5 per cent. premium). The Equitable, within six months, have increased their capital 1,000,000dols., selling such increased capital stock to stockholders at par, to pay for extensions and improvements. All the Brooklyn companies are either building additional holders or adding to their works. The present low price of gas stocks has largely resulted from hostile legislation; but the manufacturing has been so improved that the prospects look brighter for the stockholders in the future. In my opinion, gas stocks, which at to-day's prices are selling near the lowest prices they ever sold at, are the cheapest investments offered in the market—for instance, the Consolidated Gas Company alone owns real estate in New York City which would realise fully 50 per cent. present market quotations of the stock."

Cincinnati.—Incandescent lamps, says the *Western Electrician*, form an essential part of the decorations at the Cincinnati Centennial Exposition. In the floral hall the waterfall makes a fine display. There are twelve bridges from which project twenty-eight lights. In the basin of the fountain are lamps with coloured globes placed above reflectors. The effect is brilliant, although Cincinnati water is not the best medium for the passage of light; six vases filled with flowers and lighted by lamps form another attractive feature. Suspended above the floor is a flower-pot lighted by an incandescent lamp. The flowers are continually sprayed by a tiny fountain. The water is kept flowing by means of a small motor. Arranged among the flowers about the hall are concealed lights, which add a brilliant effect to the display. Surrounding the fountain in the park building are nine arches, each bearing thirty-six lamps with different coloured globes. On the ring above the fountain, where the arches are joined, are six 32-c.p. lamps with cut-glass globes. There are several "umbrella" fixtures with lamps in different parts of the hall. A rotary table bearing plants, among which lights are concealed, is another brilliant decorative feature. William J. Hammer, the electrical expert in charge of the Edison lights, is preparing a novel exhibit. It is a mammoth Edison electrical globe, composed of 15,000 of the regular electrical globes. This exhibit will be nearly 30ft. high. It will glow as one colossal lamp of 100,000 c.p. It stands on a base of about 3,200 globes, that will gleam pure white, except where the word "Edison" will flash and glow in coloured effects. There is the immense socket, 3ft. high, upholding the great globe inclosing the myriad smaller ones. From this great globe, which resembles a balloon, will come a soft radiance of coloured lights. At the front just over the base, in tablet form, is a shield which will gleam in red, white, and blue stripes, and the stars in blue field. On this shield will be the inscription in infinitesimally small globes of lettering, "Exhibit of Edison Lamp Company, Harrison, N. J.," employing nearly 15,000 Edison lamps, and illustrating the capacity for manufacture of the factory per twenty-four hours.

Reduction of Ores.—The Utah Mining and Reduction Company, says the *Scientific American*, whose works are situated at Bingham, ten miles south of Salt Lake City, are using the new "Meech process" in the reduction of their low grade and rebellious ores with success. The ore is passed through a crusher and rolls, crushed to forty mesh fine, thence into a disintegrating machine, four tons at a time, through a valve, with sufficient water and chemicals to treat the sulphur and refractory elements. Steam is then admitted to a pressure of one hundred pounds per square inch, and, at the same time, the mullers are revolved at about thirty revolutions per minute, generating electricity in such volume as to greatly assist in the decomposition of the ore. This is continued for three hours. The ore is reduced to an impalpable powder, many times finer than is possible by other methods, and is thoroughly decomposed and desulphurised. The water absorbs the chemicals, every atom of gold is made bright, and in condition for amalgamation. The pulp is now discharged into the amalgamator below, a revolving machine 7ft. long and 5ft. in diameter, in which are copper plates placed lengthwise, and, by hydrostatic pressure, quicksilver is thoroughly pressed through the ore by a "settler" of peculiar shape, having an electric copper wire broom to assist in gathering the fine amalgam before the tailings are discharged. The cost of the treatment is from two to three dollars per ton, and, as the gold ores treated run from 12 to 20dols. per ton, it leaves a handsome margin

Digitized by Google

for the owners. The ore veins are large, and thousands of tons, or enough to supply the mill for the next one hundred years, are already in sight. By this process about 90 per cent. of the gold is saved. The works occupy about nine acres of land on the banks of the Jordan River, and consist of two main buildings, 32 by 64 and 24 by 34, one two-storey boarding-house, one blacksmith shop, two 35 h.p. engines, one crusher, one roll, and other necessary appurtenances are connected with the mines by the Denver and Rio Grande and Western Railway, and demonstrate in a practical manner the immense sums that can be realised from the treatment of low grade and refractory ore dumps that have heretofore been considered absolutely worthless.

Dynamos in Telegraphy.—It is stated that the Western Union Telegraph Company are replacing batteries by dynamos for working their telegraph lines. Ten thousand cells of the Callaud or gravity battery have been displaced by the dynamos, and when account is taken of the twenty thousand wire connections of the battery, the difference of cost in favour of the dynamos in the consumption of zinc and coal, the labour and attention required, the unsteadiness of the battery currents as compared with those of the machines, the accidental openings of the batteries by reason of broken wires and defective zincs, it will be seen that the change is sure to prove a very satisfactory one to the company. The new system was devised entirely by Mr. Frank W. Jones, assistant general manager and electrician of the company, and the reports from all quarters are unanimous as to the perfect manner in which it has operated from the very moment it was set in operation on July 16. The machines, which are all of the familiar Edison type, but specially wound, are located in a commodious basement at No. 187, Broadway. Each group of eight dynamos is arranged in a substantial A-shaped frame of yellow pine, the shafts running on top of the frame, a distance of 13ft. from the base. The length of the frame is 13ft.; width, 6ft.; size of timbers, 6in. by 8in., morticed and held by bolts and nuts, so that the structure may be readily taken apart and removed at any time. All being self-contained, no jar or noise is perceptible, and a person near by is hardly aware of any motion. Two 10 h.p. New York Safety Power Company's engines are so connected up that either one is placed in action instantly by a Hill clutch to operate either one group or both at a moment's notice; a power belt connects both shafts from fixed pulleys, and is arranged to be shifted to a loose pulley. One 6 h.p. engine of the same type as the above is in position alongside of the telegraph plant, and is connected up directly to a 40-light dynamo, which supplies incandescent lamps for lighting up the large and admirably arranged operating room on the fifth floor of Nos. 5 and 7, Dey-street, directly in the rear of No. 187, Broadway, and also the office of Mr. Geo. F. Lewis, the cashier of the company, at No. 187, Broadway. An electric signal and speaking tube connects the dynamo room with the operating department, so that there is intimate communication at all times between them.

Transmission of Power.—Mr. Geo. W. Mansfield, in a paper read before the American Institute of Mining Engineers, gave some points upon the practical advantages of electricity as a motive power which will prove of interest. The following table gives Mr. Mansfield's estimate of the cost of a complete electric plant for the transmission of power to various distances, the potential at the central station being assumed to be 560 volts, with loss on line 10 per cent., copper conductors being used throughout the circuit:—

H.P.	1 mile. Dols.	5 miles. Dols.	10 miles. Dols.	25 miles. Dols.	100 miles. Dols.
1 ...	450	1,750	4,250	20,250	230,250
10 ...	2,150	7,850	24,000	136,750	2,041,750
25 ...	5,050	17,950	56,850	326,850	5,044,350
50 ...	10,000	35,050	111,750	646,250	10,058,750
100 ...	19,750	68,800	221,000	1,281,250	20,072,500
500 ...	72,800	314,100	1,066,500	6,327,500	40,122,500

The potential on which this table is calculated is very low for the transmission of large powers, but is generally used to-day for power circuits. The most expensive item in the plant is the copper, but this can be reduced by taking advantage of the fact that the cost of the copper conductor decreases as the square of the potential increases. Take, for instance, an extreme case—viz, 500 h.p. transmitted 100 miles. If we double our potential, making it 1,000 volts, the cost of our copper will decrease to one quarter, or 10,000,000dols. If, now, we again double, we decrease to one quarter again, or, at 2,000 volts potential, the cost of copper would be 2,500,000dols. The total cost of the electric plant at this potential is 2,622,500dols. Obviously there is a limit to the increase of potential; and in the transmission of such enormous powers that limit may be placed at one more doubling, or 4,000 volts. This is a possible voltage, for there are many electric light circuits in our large cities to-day of this potential, and even higher. For mining operations the use of this power will often enable work to be conducted where a steam plant for various reasons could not be operated. The dynamo can be located miles away from the mine, if necessary, on some stream furnishing sufficient power to run it. Electric motors at the mine would then do all the hoisting, pumping, and drilling, and supply the power for crushers and concentrators, and do all the hauling under and above ground. To show that this is not a mere assertion it will be well, Mr. Mansfield says, to mention what has been accomplished in this direction. There are in the aggregate, in the United States, about 125 miles of railways so operated to-day; the motors propelling loads of 10 tons, at speeds of one to 15 miles per hour, to distances of eight miles, and over grades of 10 per cent. Probably 2,000,000 passengers are now annually carried on these roads. As to size, three years ago experiments were made on the Elevated Railroad of New York City, the weight of the motor used being nine and a half tons, and capacity about 100 h.p. With this motor the four regular coaches, nearly full of passengers, were drawn over a distance of two miles, and up grades of 2 per cent., at an average speed of eight miles per hour. A plant, complete, with 30 h.p. dynamo, 20 h.p. motor, wires, insulators, &c., would cost about 3,200dols., and would do 20 h.p. actual work at a distance of a mile from the station.

Indiarubber.—Mr. Warry, of the British consular service in China, who is at present stationed as political officer at Bhama, has, says the *Times*, made a report to the Chief Commissioner on the indiarubber trade of the Mogoung district. Rubber was first exported from Upper Burmah in 1870, and until 1873 the trade was free to all. Since the latter year, however, the forests have been worked under the monopoly system, five Chinese firms being the joint *concessionaires*, two supplying the money and three superintending the work. The price ranged from Rs.60,000 to Rs.90,000 per annum, but in the present year the sale of the right produced a lakh of rupees. The

Digitized by Google

forests occupy an extensive Kachin district north of Mogoung, and stretching east across the Chinese border. The Kachins are exceedingly jealous of interference with their trees, and although at first they made the mistake of overbleeding them, they are more careful now, and though the trees seen by Mr. Warry were covered with innumerable small incisions, even up to the tiny topmost branches, they were obviously not drained to the extent of half their power. Mogoung is the headquarters of the trade; four-fifths of the yearly supply is brought in there by Kachins in the employ of Chinese, the remaining fifth is purchased in the districts by Chinese agents of the lessees. The practice is for the Chinese manager in Mogoung to make liberal advances to the Kachins to defray expenses during the collecting season; when the rubber is brought in the refund is made by selling the rubber to the manager at half the market price. Formerly the Kachins were cheated in the weighing, and they retaliated by passing off indiarubber balls, the insides of which were mostly stones and dirt. The travelling Chinese agents who also collect rubber merely travel from place to place, buying such quantities as the Kachins offer, but as the latter have no standard weights they are usually cheated to the extent of about 70 per cent. The profit on this difference of weight more than pays the expenses of the agents. In most cases rubber is the subject of certain transit charges through the Kachin districts, the tsawbwas, or local chieftains, levying a certain toll—perhaps two or three balls out of a hundred. So long as these charges do not amount to 10 per cent. there is no complaint; they sometimes exceed this, and then the Chinese protest, usually with success. An ex-chief of Mogoung, who is now a fugitive, was of great service in arranging disputes of this nature, and now a regular expenditure in presents to the chiefs is necessary in order to keep the amount of the transit dues at a reasonable level. Whatever the toll, the Chinese manager and Kachin owner bear the loss in equal shares; but the latter is amply compensated by being housed and fed at the expense of the Chinese during his stay in Mogoung. Last year a new district was opened, and a Chinese capitalist employed 400 Chinese and Shan labourers to work the forests in the neighbourhood of the amber mines. The local Kachins objected to the inroad, and insisted on their right to the forests. A compromise was reached, 200 of the labourers being sent back at once, the remainder collecting rubber under Kachin supervision, to whom 10 per cent. was to be paid, and 200 Kachins, paid at the current rate, took the places of the 200 dismissed coolies.

Electro-Motor Possibilities.—A subsidiary paragraph in the prospectus of almost every new electric company says something about distribution of power. It is, perhaps, too early in the day to hint at the possibility, that, in all probability, the subsidiary idea will ere long take first place, and that the distribution of power will bring more grist to the mill than the distribution of light. Few outside those actually engaged in business have the faintest idea as to the possibilities of the distribution of power. Only let our companies get over the primary difficulty of getting underneath the streets or above our heads with their mains, and they will find plenty of work to be done in supplying current for motors. This is what our American contemporary, the *Electrical Review*, says upon the subject, and with certain reservations, we endorse all that it says, and we are not sure but that a central station instituted primarily for the distribution of power—say, in Tudor-street—would be able to supply, within a very short period, from one to two thousand horse-power. "Just what part the electro-motor is to take in the future is a theme of engaging interest. Those who have not the time, perhaps not the inclination, to study it will very naturally content themselves with what they know or have heard of its first trials, when its apparatus was crude and complicated, its constructors inexperienced, its accomplishment at best but of trifling value. When a man sets out to explore the air and only succeeds in reaching a high altitude, his venture is set down as a failure—though, in reality, the first great step toward the accomplishment of his purpose has been gained. Only the student or the thinking man will look ahead at the splendid possibilities that he has opened the way to. No one now doubts the potency, the practicability of the steam-engine. Notwithstanding its enormous waste of power, it will turn the shafting of a great mill, propel a 10,000-ton steamer at great speed, or haul thousands of tons of dead weight along the rails. Once, however, it was a crude mechanism, its every promise laughed at even by thinking men. It required a half-century of experiment to bring it to its present state of perfection The electro-motor, on the other hand, has been under experimentation scarcely a decade, and, thanks to the indomitable perseverance and intelligence of its projectors, has made great strides on the road to perfection—indeed, many times greater than the steam-engine; and if there be any who doubt its power to supersede the steam-engine in at least an important portion of its present field, they have only to study the theory on which it is constructed, its economy, and the advantages offered by electricity as a motor, to be convinced. Mr. Frank Sprague, who has had large experience in electro-motor construction, says that, so far as trunk-lines are concerned, it is not likely for many a day to take the place of the locomotive, but agrees with other eminent authorities that it will usurp the place of the steam-engine, and in the not distant future, too, in that vast field where small quantities of power must be distributed over a wide section. In the city of New York there are thousands of small factories, mills, passenger elevators, and innumerable other demands for a constant supply of power. However small the power required, there must be an engineer and constant shoveling of coal, with its accompanying evils of ashes and dust. Think what a saving there would be in wages, in machinery, in fuel, and in the handling of fuel and its residuents, if only the power required in a single district could be generated at and distributed from a single point! One 1,200 h.p. engine would drive the shafting in over a hundred small shops, run many elevators, and the like. Instead of the 150 and more engineers and stokers, two engineers, with a few helpers, would suffice. With steam this is not possible, but with electricity it is not only possible, but practicable; indeed, it has already been accomplished in a small way, and the great scheme itself only waits upon the working out of more economical processes in the transmission of electrical energy to a distance. So rapid has been the development of electrical apparatus, that at times it seems as if one improvement had scarce time to appear in full view ere another was treading upon its heels. This being the case, the impropriety of establishing a great plant for transmitting small parcels of power before the best known method of transmission is hit upon, is immediately obvious.

THE MAGNETIC FIELD.—I.

The conception that a magnetic field contains, or, to speak more correctly, is composed of, lines of force has been so fruitful of practical results, that we have now come to look upon lines of force as an almost indispensable part of our collection of intellectual tools to be used in the solution of electro-dynamic problems. There is, however, a danger that the very simplicity of their conception may lead us to misunderstand or misapply lines of force. We are apt to make too much of mechanical analogies, and in our endeavour to represent every phenomenon by some such analogy there is a danger that we may apply mechanical and concrete notions to purely mathematical conceptions, or, so to say, ideal conceptions, which cannot properly be so represented. To the trained mathematician there is no such danger. He is used to deal with abstract ideas, and is able to always keep before his mind the boundary-line between abstract reasoning and concrete representation; but as by far the larger number of those engaged in electrical engineering are not trained mathematicians, a few articles on the subject may be useful. We propose, in the present series, first to point out some of the instances where a too concrete and mechanical conception of lines of force fails, and then, after having defined what limitations are necessary to avoid the error above alluded to, we shall endeavour to establish a practical working theory of lines of force, and show its application to some of the more important problems connected with dynamo-electric engineering. In treating such a subject it is obviously impossible to dispense entirely with mathematics, but we shall limit the mathematical treatment to what is unavoidable, and present the formulæ in the simplest possible shape.

The obvious, and, so to speak, most mechanical, way of conceiving a magnetic field is to imagine the space in which the field exists to be traversed by a definite number of lines of force, which by their density—that is, the number contained in unit area of cross-section—and their direction in space determine the magnetic properties of the field. Let us take the simplest case of a uniform field, where the density is constant over each square centimetre of cross-section, and where all the lines are parallel. Such a field might mechanically be represented by a number of threads stretched across the space between fixed points. Each thread has the property of exerting unit force in its own direction upon a unit magetic pole placed on it. Now, as the number of threads is finite, it is obviously impossible that a thread can pass through every point in the field, and, therefore, if we place the pole between two threads it would, according to our mechanical representation, not be acted upon at all. Experiment, however, shows that in whatever part of the field we place the pole, it experiences the same force and in the same direction. The lines can therefore not be absolutely fixed in space, but must have a certain power of shifting laterally to pick up poles which happen to have been placed by their side. In this case, which line shifts? That which happens to be nearest, one would naturally suppose. But how, if there be two or three lines equally near; do they all shift and lay hold of the pole placed within their reach? Obviously not, for in that case this pole would experience the joint efforts of several lines, and tend to move with a greater force than if properly placed on only one line. Here it will be seen that our mechanical analogy already breaks down. We cannot represent a magnetic field by lines like the trees in a forest, or the stalks of straw in a cornfield. If we imagine two magnetic fields so placed to each other that the lines separately considered would cross each other, we shall also see that the mechanical representation becomes useless. Imagine the exploring pole placed exactly into the intersecting point of two lines. It would then have a choice of directions, and might travel along one or the other of these two lines with equal facility. But we know from experiment that in each point of the field there is one direction, and one only, along which a free pole is urged. The crossing lines must therefore in some manner be merged into one compound line at their crossing point. But how about their separating again beyond the crossing point? The whole thing is inconceivable. We must try and find another method of representing lines of force mechanically. Such a method is easily found. Imagine the rigid lines replaced by a kind of magnetic wind or stream of some kind of matter capable of exerting force by friction or impact upon magnetic bodies, the force to be determined by the extent of surface of the body in our mechanical model, which surface we suppose to be a measure of the amount of free magnetism emanating from a magnet pole when placed in a real as distinguished from a model magnetic field. The field would in that case be represented by stream lines, its strength by the velocity of flow, and its direction by the direction of flow.

Now let us see whether the substitution of a dynamical for a static analogy has removed the difficulties of mechanically representing the magnetic field to which we have drawn attention above. First, with regard to a uniform field. This we now represent by a stream of liquid or gaseous matter having inertia, and all the particles moving in the same direction, and with the same velocity, say, a steady uniform wind. Into whatever position within the moving column we place a body, say, a sphere, to represent unit pole, we shall find it acted upon by the same force, and thus far our analogy is not open to the same objection as pointed out above for a field composed of rigid lines or threads. The case of two fields crossing each other can also be represented without difficulty by two currents flowing across each other, for they will blend and combine into one current, within which the stream lines have in each point a perfectly definite direction. In so far as the geometry of our mechanical model of a magnetic field is concerned, the analogy is perfectly correct, but as regards its dynamics we must make a reservation. It is well known that the force exerted by impact or friction of a liquid or gaseous stream upon a solid varies as the square of the relative velocity, certain minor disturbing influences neglected. But to make our analogy fit, not geometrically, but also dynamically, we must assume that the force varies directly as the absolute velocity of flow, and is independent of the relative velocity. This can be shown in the following way. Imagine the field emanating from the end of a long straight bar magnet. This can very nearly be represented in the old method by a definite number of straight lines, all radiating evenly from the pole of the magnet; and in our new way by the movement of the particles of a gas generated in the pole. To fix ideas, let us assume that by some means we arrange to have a continuous supply of gunpowder to the point which represents the pole, and that this powder is there ignited. The products of combustion from what may be termed a continuous explosion will disperse in all directions, producing a wind the straight stream-lines of which are directed away from the pole. Now, the velocity of flow must be less the further away from the pole we test it; and, neglecting disturbing influences, we shall find that the velocity, although equal at equal distances all round the pole, varies inversely with the square of the distance; and according to the ordinary laws of dynamics the force exerted upon a body placed in the way of this flow would vary inversely with the fourth power of the distance. This would, however, not correctly represent the law of magnetic attraction or repulsion. We know that the force varies inversely as the square of the distance, and to make our analogy perfect we must therefore asume that the force of impact or friction varies directly as the absolute velocity in every point, and is independent of the relative velocity between the fluid and solid body; so that when the latter begins to move the force is not diminished.

There is yet another reservation necessary to make our mechanical model a correct representation of the magnetic field. We have said that the particles of matter composing the magnetic wind or current must have inertia. This is indeed necessary in order that a mechanical force may be exerted upon the body brought within the influence of the current, for whether we regard this force as due to impact or friction, it could not exist if the moving fluid were devoid of weight. Yet if we admit this substance which flows with a certain velocity to have weight, we must allow it to be subjected to all the dynamical laws appertaining to ponderable bodies, such, for instance, as the law of centri-

Digitized by Google

fugal force. On the other hand, we know that lines of force are not subject to the influence of centrifugal force, or, at least, if such influence exists it must be counteracted by some other force, for the lines will, in magnetic metals at any rate, turn sharp corners with the same facility as they flow along a straight path. If centrifugal force existed, and were not counteracted by some other force, the lines, where they curve, would show a tendency to bulge out farther and farther, which is contrary to experience. Lines of force always show the opposite tendency—namely, to shorten themselves. We must, therefore, assume that the fluid the movement of which constitutes the magnetic current is either not acted upon by centrifugal force, or, if so acted upon, is at the same time subjected to some other force which prevents the flying outwards of the particles when moving in a curved path. Such a force might be one of attraction between particles succeeding each other in one and the same stream line, and by this assumption might also be explained the well-known tendency of lines of force to shorten themselves. Whether we accept the one or the other of these theories is immaterial; the result is the same—namely, non-intervention of centrifugal force. Moreover, we must assume in either case the existence of attraction between succeeding particles in a stream line, only to a different extent. If we allow centrifugal force, this attraction must be greater than it need be if we assume that this force has no existence. In the former case, this attraction must counteract not only centrifugal force, but also the repulsion which experiment shows to exist between neighbouring lines of force. In the latter case, the attraction between succeeding particles in one stream line need only be sufficient to balance the repulsive effect between one stream line and another. If we place over the poles of a horseshoe magnet a sheet of paper, and sprinkle it with iron filings, we obtain the well-known figure showing the lines of force. Those lines which are in the centre of the figure pass straight across between the two poles, whilst the lines on either side are more or less curved, the curvature increasing with the distance from the centre line, or what might be called the polar axis of the field. This peculiar configuration of the lines of force or stream lines, as the writer prefers to call them, is easily explainable on the assumption that there is a laterally repelling force between neighbouring lines. The lines near the polar axis being subjected to lateral pressure from all sides equally, remain straight. A little way further out the lateral pressure becomes unbalanced, producing a slight bulging of the lines. Further out still the want of balance of pressure on both sides of any particular line becomes still more pronounced, with a consequent increase of curvature, and thus the peculiar appearance of the lines, as revealed by the familiar experiment with the iron filings, is brought about.

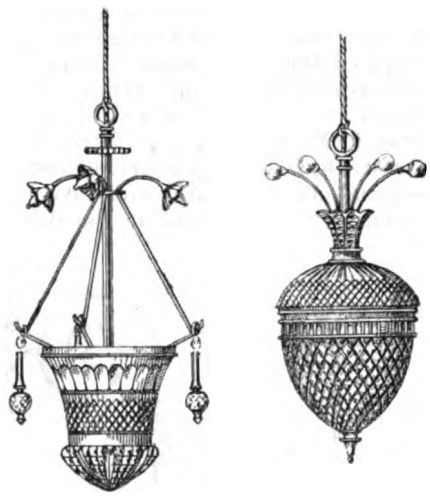
(To be continued.)

ARTISTIC FITTINGS.

IV.—F. AND C. OSLER.

In our previous articles on artistic fittings for electric light we have described and illustrated designs of fittings by professedly electrical manufacturing firms, whose business deals mostly with electrical appliances, and whose products consist of applications designed for all requisite uses as electrical fittings, and made of varying materials, brass, copper, silk, ebony, &c., combined with plain and coloured and more or less decorated glass. In our article this week we illustrate some very beautiful special designs of electric light fittings, constructed almost entirely of cut glass, made by the firm of Oslers', of Oxford-street, whose business is primarily that of cut glass manufacturers in all its branches—dining sets, chandeliers, lamps, and all manner of table fittings—but whose special department for the manufacture of cut glass electric light fittings is rapidly increasing. A large branch of business is done in this department, chiefly, of course, amongst high-class mansions and country houses, and for those who are wishing to obtain a brilliant and splendid effect, irrespective of paying the smallest amount possible for their fittings, a glance at Messrs. Oslers designs will convince them of the elegance and tastefulness of these fittings in cut glass.

Messrs. F. and C. Osler have their manufactory in Birmingham, where the various designs are prepared by a set of skilled artists and workmen, whose care and dexterity



FIGS. 1 AND 2.

may be almost said to equal that of jewellers, and who are constantly engaged in the beautiful and delicate processes of cutting the glass, and building up the various designs. The show-room of Messrs. Osler in Oxford-street is simply a palace of splendour, filled with art pottery, and long rows

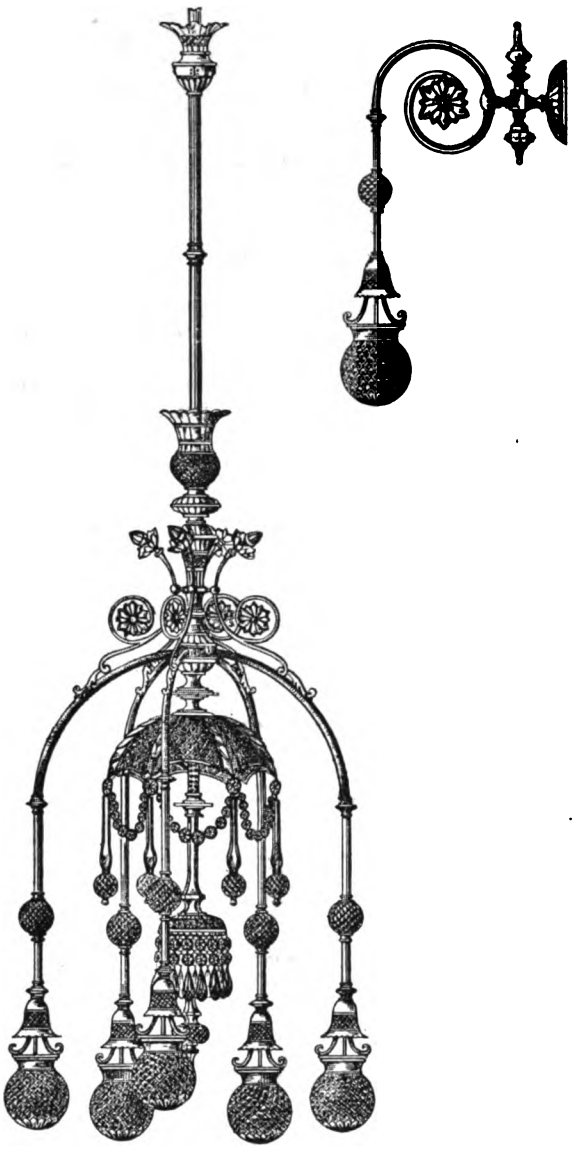
FIG. 3.

of delicate wine-glasses and table services. With these, however, we have nothing to do, and notice only the special fittings adapted to electric light. Many patterns for various positions are exhibited at these rooms, a few of the best and most typical instances of which we have attempted to reproduce, but the variety is almost endless, and, generally,

Digitized by Google

the greatest care is taken to supply special designs for each of the more important customers.

Of course it can easily be imagined that, while some of the simpler fittings in cut glass are scarcely, if any at all, more expensive than many of a similar nature in polished brass and copper, yet in many of the more elaborate and beautiful designs the cost may rise to scores, or even in some cases, hundreds of pounds for elaborate cut glass electroliers. In such cases it is not uncommon to hear that the cost of the fittings themselves exceed, or even double, the cost of the electric part of the installation. An instance has been given of a country house very handsomely and brilliantly decorated with special cut-glass fittings by Messrs. Osler, where the cost of fittings alone was over £1,000; the cost of the machinery and other apparatus would not be nearly equal to this sum. Other instances in the West End of



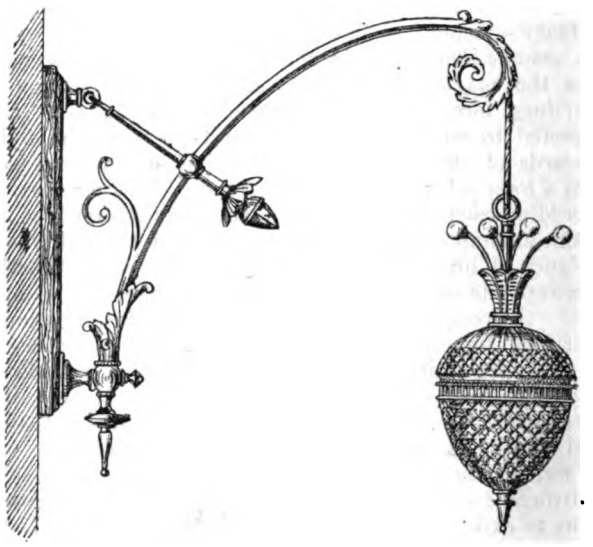
FIGS. 4 AND 5.

London, where the cost for fittings has been several hundreds of pounds, indicate that purchasers of proposed electric lighting plants are not always chary about the first cost of their fittings, provided they can obtain something equivalent for their outlay.

The effect of cut glass used in conjunction with incandescent electric lamps is exceedingly fine. It is necessary, of course, to secure the greatest effect, to keep the whole of the glass well cleaned periodically with cloths or leather; but in an establishment where constant care is given to the silver an equal attention to the fittings can be secured. When clear and transparent, the varied facets of the cut glass break up and refract the light with very beautiful effect. The glow even of the filament of an incandescent lamp is almost too concentrated to regard alone, and the blending of broken light in the clear surfaces of the cut glass is its chief charm. Besides this, there is not the loss in light with cut glass that must always attend the use of obscured or opalescent glass, and altogether a very rich and handsome effect is produced by its decorative use for this purpose.

Generally, there are two types of cut-glass fittings manufactured by this firm—namely, those in which nearly the whole design is in glass, with merely a basis of metal

FIG. 6.



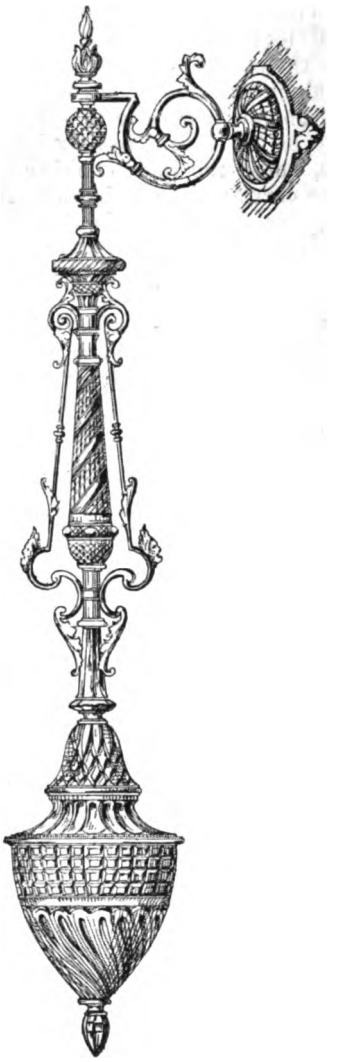


FIG. 7.

tubing upon which the design is built, and those in which the design is mainly or in great part of polished brass, with which cut-glass decorations are combined. These fittings are made in single pendants, as standards, as brackets for single, or for two or more lamps, and in large electroliers for the centre of important rooms. Messrs.

Digitized by Google

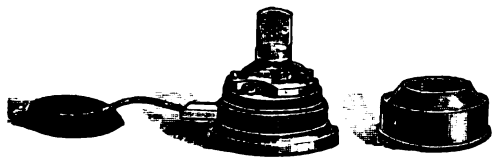
Osler also make a switch with a cut-glass cover and handle, to match the other fittings.

In our illustrations, Figs. 1 and 2, are two designs of cut glass one-light pendants. A variety of shapes of single pendants are made; these shown are, perhaps, two of the prettiest. The next illustration, Fig. 3, is of a large and handsome drawing-room electrolier for six lamps. It is made in polished brass, with cut glass globes and bowl and solid glass rods, and decorated with cut and wreathed ornaments and crystal flowerets.

The fittings for special houses are often made in various designs to match throughout. Fig. 4 shows one of these, a five-light electrolier, with pendant-shaped globes and with canopy and wreaths in cut glass, and Fig. 5 shows a bracket to match. Fig. 6 is a pretty design of suspended pine-shaped cut globe, with light wall bracket. Fig. 7 is a large and very handsome and imposing drawing-room bracket in the mansion for which they were designed, a pair of these large brackets fixed one over each end of a carved mantelpiece making a very fine decorative effect.

WOODHOUSE AND RAWSON'S SWITCHES.

Various improvements are being introduced in switches by the Woodhouse and Rawson Electric Supply Company, with the idea of obtaining special suitability for certain situations, and with the general idea of greater theoretic and practical perfection. One of these, patented by Sir David Salomons, and named by him the Broomhill Switch and Connector, has been designed for use with a portable lamp. The switch acts independently of the lamp circuit,



The Broomhill Switch and Connector.

while, by using the connector itself as a lever, the portable lamp can be switched on and off without taking out the connector.

CORRESPONDENCE.

ELECTRIC TRAMWAY WORK.

To the Editor of The Electrical Engineer.

Sir,—As none of our electrical tramway engineers have replied to your correspondent's request, perhaps the following information may assist him as to what he is desirous to find out.

For his information I may say, that about six years back, as near as I can remember, I witnessed some experiments in electrical traction at Leytonstone, carried out by Mr. Radcliffe Ward on behalf of M. Phillippart, who, I believe, introduced into England the Faure type of accumulator.

The vehicle used for these experiments was a slightly-built car, either of French or Belgian manufacture; the motor used was of the well-known Gramme type, and, as far as I can remember, the batteries of the Faure accumulator type were placed on the top of the car.

The experiments were somewhat crude, but quite sufficient to show that electrical traction had a great future before it, especially when more fully developed.

I may also say that M. Julien, of Brussels, publicly ran an electrical car during the Antwerp Exhibition, held in 1885, upon which I rode some dozens of times with considerable pleasure, as this car ran very successfully, although the batteries were charged under great difficulties from an ancient type dynamo, and a very shaky old engine, and bad belting. The whole plant was only worth about £50, which fact, I think, should be good evidence that electrical traction with modern motors and improved batteries can be made to become, in the hands of practical men, a good paying industry for capital invested.

I believe Dr. Finny, an American, ran the first electrical car by overhead conductors, either in the year 1881 or 1882, at Pittsburgh, U.S.A., his patents are now owned by the Overhead-Conductor Electric Railway Company.

Dr. Finny appears to be one of the earliest experimenters in electric traction. There are records of his work dating as far back as 1878.

I have some slight idea that Profs. Ayrton and Perry, also Dr. Woodward, experimented in traction work in 1883 or 1884. I cannot remember the exact dates, but I have no doubt the above-named gentlemen can do so if applied to by your correspondent.—Yours, &c.,

A. Shippey.

INSTITUTE OF MEDICAL ELECTRICITY.

To the Editor of The Electrical Engineer.

Sir,—With reference to the letter of Mr. Newman Laurence which appeared in your last issue, I venture to trouble you with a few remarks on the subject.

The wonderful efficacy of electro-magnetism as a means of cure in all acute and chronic diseases is fully recognised, though not so widely known by the general public as it ought to be; and if an institute of medical electricity could be established somewhere in the West End and the best apparatus only used, I am satisfied an incalculable good to suffering humanity would result—even the death rate would be materially reduced. It is well known to all who have been under treatment that the electric current drives out of the system through the pores or other channels all deleterious matter, and is useful in almost every disease, reaching to parts not even known to be affected, without, however, lowering the system like drugs or the Turkish bath. The treatment is not only powerfully tonic, but also gently and naturally stimulating, and it almost always induces refreshing sleep, which those who are afflicted with insomnia should note.

The current may be applied free from shocks of any kind, so that the most sensitive or nervous person can take the treatment without any risk or fear.

It is, perhaps, worthy of consideration by the promoters of the institute whether it would not be advisable to incorporate it in, or amalgamate with, the Electro-Therapeutical Society, established some years ago in Eastbourne-terrace, of which Edward Herford, Esq., J.P., coroner for Manchester, is the chairman, in order that a strong and influential directorate may be formed, and I shall be glad to hear the views of those more immediately interested on this point.—Yours, &c.,

Alpha.

August 22nd, 1888.

ELECTRIC CURE.

To the Editor of The Electrical Engineer.

Sir,—As you have most usefully opened your columns to the discussion of this great subject, I hope you will let me send you particulars of a society formed for a kindred purpose to the institute which you have recommended. The society, you observe, has the support of many good men, united solely by a sympathy for suffering humanity. I could say much of my well-known (almost perfect) cure from complete prostration by paralysis, and of cures similarly effected from varied ailments amongst my friends. You will, perhaps, permit me to mention, from my own knowledge, what seems almost a miraculous case of a gentleman suffering three or four years ago from chronic rheumatic gout, progressive paralysis, enervation, &c. He was entirely helpless—hands and fingers drawn out of shape, legs and feet powerless. His physicians said his case was utterly hopeless; but his friends applied to Mr. Grigg, by whom he was treated twice a day for nine months, and recovered perfect use of his limbs and powers. He was married soon after, and has now a son and heir.

I have no right to trouble you with other illustrations of Mr. Grigg's powerful curative agency; but I submit that we, and your readers, are entitled to have this system put at least *pari passu* with that which you have especially favoured, and as against such as you truly designate quackery, conducted for commercial purposes.—Yours, &c.,

Edward Herford,
J.P. for Lancashire and Coroner for Manchester, Chairman of the Electro-Therapeutical Society.

THE
ELECTRICAL ENGINEER.

Published every Friday.
Price Threepence; Post Free, Threepence Halfpenny.
Editorial and Publishing Offices:
139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months.	12 months.
nited Kingdom.....	3s. 3d. ...	6s. 6d. ...	13s. 0d.
Within the Postal Union	4s. 4d. ...	8s. 8d. ...	17s. 4d.
Other Places.....	4s. 10d. ...	9s. 8d. ...	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, ESQ., *President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of* W. H. WOLLASTON, M.D., F.R.S., *and on April 20th we gave that of* SIR HUMPHRY DAVY, F.R.S., *whose fame as an electrician is still more prominent than that of* WOLLASTON. *Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that* PROF. D. E. HUGHES, F.R.S.

TRACTION.

Elsewhere we give a report upon the Lineff electric traction system as applied to a short experimental line upon the West Metropolitan Tramway. The figures as given by Mr. Kapp are the result of direct experiment, and thus far more valuable than others which are deduced from theory. The introduction of electric traction seems to be the most important development of electrical work in the near future. We recently referred to a syndicate whose object is to introduce electric traction upon the Metropolitan Railway, another to exploit the series motor system, while Messrs. Crompton and Co. are carrying out experiments for the Elieson Company. The Brush Company, again, has work in hand, the Lineff Company has been registered, and the Southwark Subway will probably be worked by means of electricity. Other schemes are under discussion, and thus the report of Mr. Kapp comes at an opportune moment. If the promoters of the Southwark Subway had intended to provide a line most favourable to electrical work, they could hardly have done better than they have, and it remains to be seen how electrical engineers will use the opportunity. The result depends very much upon directing the directors, as if they will but employ a competent engineer and fight more or less shy of patentees and hobbies, they will achieve a success that will amply remunerate them and their shareholders for the faith they place in the capabilities of electricity to provide a certain, safe, and economical motive power. Of the three electrical systems at present in vogue, there is no reason why the best and cheapest in every respect should not be applied satisfactorily in this subway. The three systems referred to are respectively with overhead conductors, with underground conductors, and with accumulators. Our American friends have again and again stated that the cost of the overhead system to that of the underground is about as one to ten, and if that is correct, instead of the item £2,000 per mile appearing in the estimate for capital expenditure, only about £200 per mile for insulators, brackets, etc., will appear. This amount indeed seems ample, and it would not be surprising to find the actual cost reaching no more than half this amount. The bugbear which electrical engineers have not as yet had to contend against is the question of leakage, and a subway of this kind will not conduce to good insulation, therefore it may be found advisable to increase the capital expenditure somewhat, if by that means better insulation can be guaranteed from the start. Unfortunately, the amount of leakage cannot be foretold; if it could, the question would immediately resolve itself into a comparison of the cost of the leakage annually with the interest upon the capital expenditure undertaken to avoid leakage. It may be cheaper to have a certain small leakage than to go to any great initial expense to do away with it.

Digitized by Google

Our meaning here must not be mistaken. There is no intention of advocating the putting down conductors in so careless a fashion that leakage will necessarily be large. This idea may be illustrated somewhat as follows: Leakage is inevitable. Assume that in a well-considered installation it is six per cent. To reduce this loss to five per cent. may be more costly than allowing it to remain at six per cent. With regard to Mr. Kapp's experimental results, the insulation test of this particular line gives no information as to a similar test on another line. This is all we know, that the insulation resistance is the resistance of a shunt circuit through which as little current as possible is desired to pass, for what does pass is waste and lost so far as the immediate work in hand is concerned. What the *minimum* insulation resistance per mile should be with overhead or underground conductors is a matter which, at present, is generally unsettled. That it should be high, all agree, but where "bad," "fair," "good" and "excellent" begin or leave off is left to individual opinion. An argument upon such a datum as this might well form the discussion of the electrical section of the London Chamber of Commerce. A point which is exceedingly interesting is to be found in the figures from which the traction resistance is obtained. In the schoolboy days of Macaulay the traction per ton was given by schoolmasters—that is, by text-book compilers and readers—as 8lb., and no doubt many a student assumes this to be about what would be experimentally found in tramway work. Those who have had something to do, practically, with such work know that it may be anything, from 20lbs. to 80lbs., according to the varying conditions of the rails. In Mr. Kapp's experiments it was between 50lbs. and 60lbs., and as we may assume the conditions to have been somewhat favourable, all future calculations as to power required must provide for a good margin of safety over and above this. In applying electric traction to the Southwark subway, the varying condition of the rails will not be so great as in ordinary street traffic, and the traction may therefore be taken as almost constant. It may be mentioned here that there seems to be an error in the figures of the report, probably typographical, in that $20 \times 230 = 4{,}600$ watts do not represent 7·5h.p. The number should be 5,600, and the pressure, instead of 230, should evidently be 280 volts. The necessary corrections being made due to the use of the overhead system, an approximate estimate of capital outlay can be obtained from Mr. Kapp's figures. We believe the results of Mr. Lineff's experiment on the West Metropolitan have been so successful as to induce the company to give the system a fair working trial, and it was for the purpose of obtaining the necessary capital to carry out the contemplated work that the company was recently registered. There is only one more point in the report upon which we would remark, and that refers to the estimated plant required. The estimate for steam power seems to be far in excess of the requirements. Two engines nominally of 45h.p. each should develop under normal working condition from 2·5 to 3 times their nominal power, and this would give from 230 to 270 actual h.p. to work the traffic. Perhaps we have misread the meaning, but it seems to us that either of the engines specified could without difficulty drive the three dynamos—at any rate, there is here an ample margin of power to satisfy any demand.

LEAVES FROM THE DIARY OF A YOUNG ELECTRICIAN.

BY BROAD BENT.

April 1, 188—.

YOUNG Electrician wanted immediately, to take sole charge of an incandescent installation.—Apply by letter, stating age, experience, and wages required, to X. Y. Z., office of this paper.

An answer to the above advertisement, which appeared in a technical journal a week ago, is the explanation of my being here. When I saw the advertisement, I repeated to myself, "'State wages required'—um, I don't quite like that clause. Why did they not say, 'Lowest tender accepted,' I wonder?" However, I am here now, and on the first page of my diary I will jot down a few particulars of the installation.

The generating plant consists of a Lancashire boiler (19ft. by 6ft.) with Galloway tubes; a horizontal fixed engine, 20 h.p. nominal (worked up to 40 h.p.), with feed pump attached, worked from an excentric on the main shaft; two 15-unit dynamos, capable of giving 170 volts and 90 amperes each, coupled in parallel and mounted on rails.

The generating station, which we call "the shed," is fortunately in the open, so that we get a little fresh air occasionally, although the installation itself is underground. The main cables (19-16s) extend to a distance of a mile and a-half to the right of the shed, and to about a mile on the left, being supported in the tunnels upon earthenware insulators, which are fixed upon iron brackets projecting from the wall. Originally the cables were fixed to the walls by "dogs," but as water is constantly trickling, and in some places pouring, down the walls, the insulation became saturated, and considerable loss of power was the result. At five points along the line the mains are "tapped," branch cables of 19-21s being connected and led away to five stations, taking on the average 60 lamps each. In the stations the cables are suspended overhead, parallel with the platforms, the lamps hanging from them at distances of about 30ft. apart. Wires are tapped on to these branch cables to feed the lights upstairs, switches being inserted where necessary, and double-pole fusible cut-outs are placed at the commencement of every circuit of three or more lights

The machinery runs twenty hours every day, so we work in "shifts" of twelve hours; a night and day shift. The average current in the daytime is about 85 amperes in the summer, and about 140 amperes at night. In winter there is very little difference between night and day currents. (Fig. 1 shows the positions of the five stations.)

April 5.—Tested the insulation of the cable this morning, after the machinery stopped (that is about 1 o'clock). Not supposing it to be very high, I used the ordinary bridge method (see Fig. 2.) I, of course, had to cut out all the stations first, which means walking through the two and a-half miles of tunnel, with a smoky hand-lamp, which has a bad habit of getting blown out just when it is most required. However, after falling over the points a few times, I got on fairly well.

I was somewhat surprised to find that the longest cables —those on the C.S. side—gave the highest insulation

Digitized by Google

resistance; in fact, it was almost twice as much as the S.M. end. The actual figures were—

C.S. side = 19,000 ohms, when connected as in Fig. 2.
„ „ doubtful* „ „ „ Fig. 3.
S.M. side = 12,000 ohms, „ „ „ Fig. 2.
„ „ 8,000 ohms, „ „ „ Fig. 3.

The earth connection was made by soldering a wire to the water-pipe. Being then about 4 a.m., it was time to plug in the stations again and get ready for lighting up.

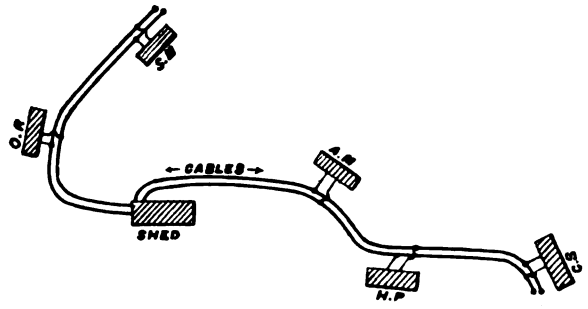

Fig. 1.

Whilst in the tunnels I examined the cables, to find, if possible, the cause of the difference in the insulation resistance of the two sections. I found that near S.M., for a distance of several yards, the wall was quite wet, and water was dropping from the roof on to the cables, the insulation of which was completely wet through. Besides this, all the insulators were covered with a thin layer of damp soot, thus forming a probable source of leakage.

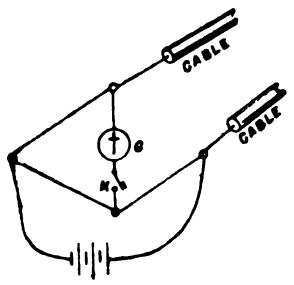

Fig. 2.

On my way back to the shed, I stumbled over a guide-rod and extinguished my lamp; not having a match I had no alternative but to accomplish the remaining distance—almost a quarter of a mile—in total darkness.

April 12.—I sent a man to clean all the insulators in the tunnels a day or two ago, and also to paint the cables from end to end with a mixture of tar, pitch, &c. This has increased the I.R. considerably, especially of the S.M.

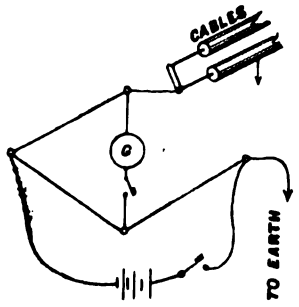

Fig. 3.

section. I should like to take the insulation resistance from lead to return of the whole installation—not the cables only, but including everything, as I think there is a loss of about 5½ h.p., when all the lamps are on, through leakage alone.

Thus the lamps are 160 volts, 16 c.p., which at 4 watts per candle is 64 watts per lamp. As $W = E C$, $C = \frac{W}{E} = \frac{64}{160} = \cdot 4$ ampere per lamp. So that when the 300 lights are on the total current should be $300 \times \cdot 4 = 120$ amperes. As a matter of fact, at the present moment the current passing through the ammeter is 140 amperes, and there are 285 lamps in use, which represent a current of 114 amperes—there is a loss of 26 amperes.

Using the formula $\frac{E C}{746} = \text{H.P.} = \frac{160 \times 26}{746}$, I find there is a loss of about 5·57 h.p., not including the fall of potential along the line, which is about 15 volts.

Unfortunately, there is not time to take the insulation resistance of "over all" and find out the weak points, as this would mean taking down the 300 lamps and replacing them all again (besides making the test) between the hours of 1 a.m. and 5 a.m., and if we chance to be a few minutes late in starting there would probably be five reports (one from each station) sent to head-quarters.

(To be continued.)

* The readings were recorded very roughly at the time, in pencil, on a scrap of paper, and this is illegible. As nearly as I remember, it was some thousands less, having only half the thickness of dielectric in circuit.—B., 1888.

ON THE PROPER SIZE OF TELEPHONE CONDUCTORS.

BY DAVID BROOKS.

The long-distance telephone company work metallic circuits of No. 16 American gauge between Philadelphia and New York, the length of conductors being slightly over 200 miles, the distance by line being 100 miles, four miles of which are under ground or water, making eight miles of conductors under ground and water. The telephones work well—far better, indeed, than the local service in the city for even as short a distance as one quarter of a mile, even if they use the same gauge conductor. With the metallic circuit, the resistance is fully eight hundred times that of these short lines. I mention this to show that conductivity or low resistance has very little to do with good telephonic service. In the one instance we get rid of inductive disturbances, and in the other we do not.

Take an ordinary circuit, say, one mile in length. Say that each receiver has a resistance of 100 ohms, and the induction coil 300 ohms, making a total of 400 ohms for the resistance of one instrument. Calling the conductor 20 ohms, we have a total resistance of 820 ohms in the circuit. Now, substituting a No. 21 gauge conductor, which has a resistance of about 70 ohms per mile, we have increased the resistance of the circuit about 6 per cent., and theoretically increased the magnetic effect 6 per cent. Now the No. 16 gauge wire has twice the surface of the No. 21 gauge, and gathers twice the quantity of inductive disturbance. It has twice the electro-static capacity, and twice the retardation, if electro-static capacity and retardation are identical.

There is no trouble hearing the voice in these short circuits in either case, but the difficulty lies in getting distinct articulation. As an illustration, we have a telegraph cable of 53 conductors on the Pennsylvania Railway, between Broad and Thirty-second streets, a distance of 1⅓ miles. Twenty-eight of the conductors are in use, mostly for telegraphic purposes. The other twenty-five are idle. Using one of the wires with the telephone, it works fairly well, but if we bunch all the idle wires at each end, and use them as a single conductor, we reduce the resistance of the conductor twenty-five fold, and we increase the inductive disturbances to that extent, and develop a noise resembling that of a million promiscuously-tuned Chinese gongs. We can get no speech over that bunched conductor.

There is another view which may be taken of the cases and the effects ascribed to self-induction, or as our European electricians now express it, "electro-static inertia." In reference to that phenomena I will quote from Dr. Oliver J. Lodge. He states: "There is a remarkable fact concerning electrical currents of varying strength, which has been lately brought into prominence by the experimental skill of Prof. Hughes—viz., that a current does not start or stop equally and simultaneously at all points in the section of a conductor, but starts at the outside first. The fact is naturally more noticeable with thick wires than with thin, and it is especially marked in iron wires. . . . To illustrate this matter further, rotate a common

Digitized by Google

tumbler of liquid steadily for some time and watch the liquid, dusting powder, perhaps, over it to make it more visible. You will see first the outer layer begin to participate in the motion, and then the next, and then the next, and so on, until at length the whole is in rotation. Stop the tumbler, and the liquid also begins gradually to stop by a converse process." Again, he states: "We learn from all this that whereas, in the case of steady currents, the sectional area and material of the conductor are all that need be attended to, the case is different when one has to deal with rapidly-alternating currents such as occur in a telephone."

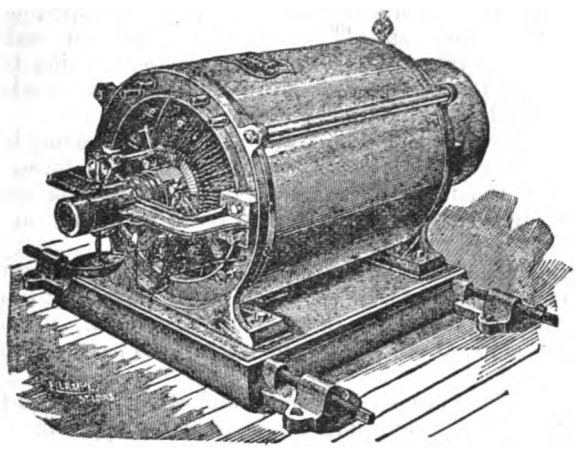
I am not familiar by practice or experiment with electro-static inertia, but infer from what I read that it is unfavourable for the use of large-sized conductors for telephone purposes. I am firmly in the belief, however, that small conductors, when used for ordinary lengths, are far preferable to those that have been heretofore employed. That for overhead wires strung on poles or housetops, a phosphor bronze conductor, on account of its strength and small diameter, is far superior to iron or copper, because it can be made with very small diameter and yet have sufficient strength and conductivity. I believe also that there have been thousands or hundreds of thousands of dollars spent for copper which could have been saved and a better service obtained by using smaller sized conductors.

Before the conductors referred to in the iron pipe were connected to the overhead conductors, a number of experiments were made with telephones, using the iron pipe for the return circuit, so as to compare its effect with that of the complete copper metallic circuit. No inductive disturbance was perceived in either case, nor did the copper metallic circuit show any advantage over the circuits using the pipe for the return current. In the centre of the cable is a smaller sized wire, No. 18 American gauge, upon which we still use telephones; and although there are heavy dynamo currents upon four of the No. 16 conductors in the same cable, or group, the No. 18 conductor for telephone purposes using the pipe for the return circuit works much clearer and better than any of the circuits of the local telephone company whose wires are strung upon poles or house-tops.

And this brings to my mind a suggestion of Oliver Heaviside, that electro-static inertia, or self induction, might be neutralised by mutual induction, since it does appear that the iron pipe has something to do with the good working of the telephone conductor.—*Electrical World.*

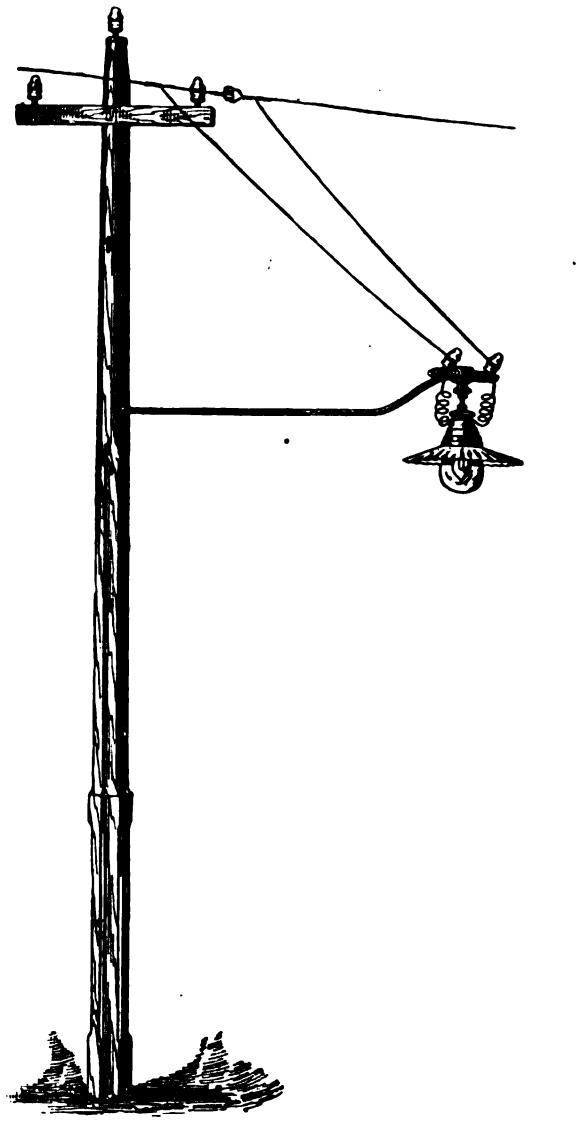
THE HEISLER SYSTEM.

The Heisler system of street lighting, now in use in several towns in America, differs from most others in this important point, that it is an incandescent system and not an arc system. We have already commented upon this system in our issue of July 20th (p. 49), and to-day we add a few particulars concerning this system, which, curiously enough, seems to be supplanting the "tower" system in some cities. The plant for the street lighting of Wabash, Indiana—where the "tower" system has been in use for over eight years—was completed recently, consisting of one hundred and thirty-two lights of 30 c.p. placed at the intersection of the streets. The circuits extend over an area of 12 miles, No. 8 wire being used throughout. The street fixtures are directly attached to the poles in substantial fashion, supported by iron castings made for that purpose, each light being at the height of about 12ft. above the ground.



The Heisler Incandescent Dynamo.

Wabash was the first city in the United States to adopt the tower system for the illumination of the streets. It was not, however, so successful as had been anticipated, the strength of the lights casting many of the streets into deep shadow, and an improvement was sought in the direction of better distribution of light by using a greater number of lights of smaller candle-power at a regular and suitable distance from each other, and of obtaining an equal amount of illumination in every part of the city, no matter how remote from the centre.



The Heisler Street Fixture.

A local company was formed for the purpose of supplying the street lights and private firms from one central station by incandescent lights on this system. The steam plant which had been used for the arc lights on the tower, consisting of a 45 h.p. engine and a 50 h.p. boiler, was turned over to the company, and has proved sufficient to supply not only the street illumination over the whole extent of the city, but also a plant of about 200 lights of 20 and 30 c.p. for shops and private residences. The local paper says: "There is no denying the fact that the present illumination is a great improvement over the tower plan, as used by Wabash for nearly, if not fully, eight years. The Heisler light is suitable for both street and indoor illumination, and the large number of lights now used insures a more thorough illumination of the city than could possibly be obtained by the other plan."

Digitized by Google

The dynamo is shown in our illustration. It is a high-tension alternating-current machine, wound for a constant current, and automatically regulates itself if any of the lamps go out. The lamps used are nearly all 32-c.p. incandescent lamps, though 25, and 40, and 100 c.p. lamps are also used where required. They take the full current, and a bye-pass is obtained by the simple method of inserting a thin film, which is broken by the high-tension current if the lamp goes out, thus short-circuiting the lamp. A very large duty is claimed for the system, seven lamps of 30 c.p. being obtained per h.p. Twenty-four central stations have been established on this system during the last year, all of which are said to be paying.

REPORT OF MR. GISBERT KAPP ON THE LINEFF SYSTEM.

To the Chairman of the West Metropolitan Tramway Company—

Dear Sir,—I have examined and tested the electric tramway line on the Lineff system, which has been laid down for experimental purposes at the Chiswick depot of your company. The car is a small open car, fitted with a 4 h.p. (nominal) Immisch motor. The transmission of power from the motor to the car wheels is by means of a countershaft and two Renold's chains, and, in this respect, does not differ from that used on other electric cars. There are, however, two special appliances peculiar to the Lineff car. The one is a movable dash board at each end of the car, which upon striking an obstacle automatically reverses the direction of rotation of the motor, and causes the car to run back; and the other is a magnetic brake.

The object of the dash board and automatic reversing gear is to more quickly stop the car, if through the negligence of the driver it should run into an obstacle. In this case the dash board causes the brake to go on, and the motor to be reversed. The putting on of the brake is a good feature, but I do not consider the advantages of automatically reversing the motor sufficiently great to compensate for the complication which the arrangement entails.

The magnetic brake can also be put on by hand, being actuated by the same switch lever by which the driver controls the speed of the car. I consider this brake an extremely valuable feature of the Lineff car. When the car was fully loaded and running at full speed, the distance traversed after cutting off the current and putting on the brake was only 9ft. It is needless to say that no hand-brake could effect a stop in so short a distance. As it is, however, not always necessary to stop so quickly, the switch controlling the brake-magnet should be provided with intermediate contacts and resistance coils, to enable the driver to stop more slowly if desired.

The experimental line is about one-tenth of a mile in length, and is provided at one end with a crossing point, having the usual automatic switches, so that the car runs out on one side, and home on the other side. The curves are very sharp—one having only 21ft. 6in. radius—and the line is rather in a bad condition throughout, being built mostly with old and discarded rails, so that the power required to propel the car is much greater than would be the case on a good line. Although a car of that size would be usually drawn by one horse, on the experimental line one horse is hardly enough to move the car on the sharpest curve, where the pull as measured by a dynamometer reached 380lb. This is the reason why the power required to work the car as given in the appendix is rather greater than would generally have to be provided for a car of that size. I have, nevertheless, based my estimate for the plant required for the Kew Bridge-Hammersmith line upon the data obtained in my tests with the small car, in order to have ample margin of power. This estimate is given in the appendix.

The Lineff tramway system belongs to that class where the current is supplied to the car by means of a conductor placed underground, but whereas, in other systems, the metallic surface of the conductor is exposed along its whole length, and a contact brush or slider rubs along it to take the current off, but in the Lineff system nearly the whole length of the conductor is insulated, and the current is taken off at certain points, about three feet apart. At these points are fixed small saddle-shaped contact pieces, over which trails the bight of a metallic rope, suspended from shoes which pass through the slot of the channel, and are attached to a flexible beam under the car. The rope consists of a stranded wire cable protected with gunmetal ferrules, which can be easily renewed when worn. It is insulated from the shoes which pass through the slot, and the connection between it and the main controlling switches is also insulated. The rope in passing over the contacts collects the current, which is thus led to one of the main controlling switches, and from there to the motor, returning through the framework and wheels of the car to the rails. The great difficulty with all underground conductors for tramways is their insulation. A cable protected by insulation over its whole surface may be buried in the ground, and no escape of electricity can take place. If, however, the insulation is removed at certain points along the cable, so as to expose at intervals the metallic surface, electricity can escape at those points, and it is evident that the escape will be the greater the more the conductor is bared. A conductor only partially insulated cannot be simply buried in the ground, but must be supported on insulated brackets clear of the surrounding ground or masonry. Even if so supported, a certain amount of electricity is lost by leakage, and, generally speaking, the loss will be in proportion to the metallic surface exposed. Now, in other systems of underground conductors, the metallic surface is exposed from one end of the line to the other, and the leakage resulting therefrom must obviously be very much greater than with Mr. Lineff's arrangement, where nearly the whole of the conductors may be covered by insulation, and only a few inches of metallic surface are exposed at intervals. It is doubtless due to this arrangement that the insulation resistance, even after the very severe test described in the appendix, was yet found to be as high as 10,000 ohms, being at the rate of 1,000 ohms per mile. With this insulation resistance, the loss of current over a double line between Kew Bridge and Hammersmith would not reach two amperes, and the power wasted would amount to about three-quarters of a horse-power, or about 1 per cent. of the power required to work an eight minutes' traffic over this line. I know of no other underground system which comes anywhere near this in perfection of insulation.

Another advantage of the Lineff conductor is the facility with which crossings can be arranged. The conductor consists of iron piping, with a copper conductor inserted. The saddle-shaped contacts are screwed into the pipe, which is sub-divided into sections, each sufficiently short as not to be influenced by changes of temperature. Connection between adjacent sections is made by short pieces of insulated cable, and it is thus an easy matter to arrange for two conductors to cross each other without interference. Such crossings have been fitted at one end of the experimental line, as already stated; and I found the car and its collectors to take these crossings easily, the working being facilitated by the ingenious manner in which the shoe beam is attached to the underside of the car.

The direction of motion is controlled by a reversing lever, and the speed by a switch lever. Ordinarily, during the journey, the driver has therefore to attend to one handle only, by which he controls the speed and puts on the brake.

Having carefully examined and tested the Lineff system, I have come to the conclusion that it is superior to other systems employing an underground conductor, and that it will be found suitable for suburban lines having a heavy traffic.

The results of my experiments and estimates of the Kew Bridge-Hammersmith lines are given in the appendix.

Appendix to Report on the Lineff Tramway.

Object of Experiments.—The object of my examination and experiments were, in the first place, to ascertain the electrical condition of the experimental line laid down on the Lineff system at the depot of the West Metropolitan Tramway Company; and, in the second place, to estimate what amount of steam and electrical plant would be required

Digitized by Google

to work on the same system a given line adapted for a definite traffic.

Instruments Used.—All resistances were taken by a Wheatstone's bridge and mirror galvanometer, whilst current and pressure were measured by Miller's patent ampere and volt meters, newly calibrated.

Insulation Test.—This was made by measuring the resistance between the rails, which carry the return current, and the central conductor, which carries the outgoing current. During these tests the car was placed in the shed, and that portion of the conductor which is within the shed was disconnected, so that leakage by current through the switches and various connections in the car should not interfere with the test. The insulation resistance of the whole conductor was found 25,400 ohms. As this insulation resistance necessarily depends to a certain extent upon the state of the atmosphere, and must be lower in wet weather, I determined to test it under the most unfavourable conditions possible; and for this purpose I ordered an attendant to play into the central channel from a water hose, and another attendant to throw buckets of water over the slot all along the line. Under this treatment, which was intended to imitate a heavy shower, the insulation and resistance gradually diminished until it reached 10,000 ohms, after which point there was no further reduction.

Resistance of Conductor.—The resistance of 174 yards of conductor was found to be ·170 ohms. The calculated resistance of copper wire within the pipe is ·240 ohms, so that the resistance of the iron pipe must be about ·580 ohms.

Resistance of Earth Return.—The resistance of 174 yards of earth return circuit formed by the tram rails, the girders of central channel, and the earth, was found to be ·145 ohms. This, at the rate of 1·47 ohms per mile, was very much higher than I expected to find. The probable reason for this high resistance is that the material of the rails and girders has not been specially selected with regard to its electrical properties. The rails utilised in the experimental line were worn out and discarded rails of various patterns. According to the chemical composition of steel, its resistance may vary from six times to about forty times that of copper, and it is quite possible that the high resistance of the return circuit is entirely due to the particular quality of which these old rails consist. Rails can now be obtained of steel having about seven and a half times the resistance of copper, and if this steel be used, the resistance to the return circuit need not exceed ·25 ohms per mile.

Power Test.—The car employed was an open summer car, carrying 20 passengers, besides driver and conductor. I estimate the weight of car, as fitted with a 4 h.p. Immisch motor and chain gear, magnetic brake, and other accessories, at 35cwt., without passengers. The line consists of a straight portion, a curve of fairly large radius, and a crossing point, over which occur very sharp curves, one of only 21ft. 6in. radius. Owing to the rails being worn, and originally of different patterns, the wheels ran at times on their flanges, which causes a greater resistance to the motion than would be the case on a properly-built line. To find the electrical energy required to propel the car, I observed the pressure and current whilst the car was travelling up and down the line, over the straight portion and the curve, but not over the crossing points, because when passing these the current underwent such rapid variation that it was impossible to obtain correct readings. In all there were made ten runs, with the car containing only three persons, and the average current for the straight and curved part of the line, and for the slight rise at either end, was 11 amperes, at a pressure of 231 volts on the motor terminals, when the car was travelling at full speed, or about seven miles per hour. The energy supplied to the car when running light was therefore 3·4 e.h.p. The car was then loaded with 40 cast-iron rail chairs, weighing 86lb. each, and in addition carrying two persons, the total load being 33½cwt., and ten runs were made. The average current required was now for full speed thirteen amperes, at a pressure of 230 volts on the motor terminals, corresponding to an electrical energy of 4 h.p., for a total rolling load of 3·4 tons.

Power Required to Work a Full-Sized Car.—The average electrical energy which will have to be supplied to each of a number of cars running simultaneously can be compiled on the basis of these experiments. I make no allowance for the following considerations—viz.: 1. The tractive force per ton of rolling load will be less on a properly-constructed line, with rails in good condition. 2. The efficiency of the motor and gear in a large car must be greater than in a small one; and 3. The car does not always carry its full complement of passengers. All these points tend to reduce the power required, but I leave them out of consideration in order to have an ample margin of power. A full-sized car capable of accommodating 46 passengers, and fitted with electric gear, will weigh about three tons, and the passengers, with the driver and conductor, represent an additional 3·4 tons, so that the total rolling weight will amount to 6·4 tons. The electrical energy which has to be supplied to propel this car at a speed of seven miles per hour is, therefore, $4 \frac{6 \cdot 4}{3 \cdot 4} = 7\frac{1}{2}$ h.p.

This is represented by a current of 20 amperes and a pressure of 230 volts.

Plant required for working a double line between Kew Bridge and Hammersmith, with an eight minutes' service, six or seven cars being simultaneously in motion. The gradients are only trifling, and need not be taken into account where the current is divided between several cars. The maximum current required for seven cars will be 140 amperes, and the pressure 300 volts, allowing 20 volts loss along the line. The conductor will consist of a ¾in. gas tube, with a central No. O B.W.G. copper wire or bare cable of equivalent area. The resistance of the conductor and earth return formed by the rails and channel girders will be ·75 ohms per mile. At the depôt there will be three dynamos, each having an output of 30 h.p. (electrical), and three steam-engines, each of 45 h.p. Two sets to work the traffic, and the third in reserve.

With a Four Minutes' Service, fourteen cars will be simultaneously in motion. The conductor will consist of 1in. gas pipe, with a 19 strand No. 11 bare copper cable. At the depot there will be three dynamos, each having an output of 60 h.p. (electrical), and three steam-engines, each of 80 h.p., two to work the traffic, the third being in reserve.

Capital Outlay.

In estimating the cost of plant required to operate this line, I leave out of account the cost of buildings and permanent way, as both items are approximately the same as for horse traction. The building for the machinery will be less costly than the equivalent stabling; but, on the other hand, the permanent way will be slightly more expensive for electrical traction on account of the greater care which will be required in making good electrical connection between adjacent rails and the side rails, and the central channel girders.

Thus we may take it that the total expense will remain about the same. As regards the cost of the central channel, I take this to be £2,000 per mile, which I understood is the figure arrived at by Mr. Lineff, from his actual expenditure incurred on account of the central channel on experimental line.

Cost of plant and reserve gear, including foundations and labour for a service of

	8 min.	4 min.
Central channel	£12.000	£12,000
Conductor	2,280	3,060
Boilers, engines, belt, feed-heaters, &c.	2,200	3,500
Dynamos, switch-blocks, instruments, &c.	1,000	1,500
Cars fitted with motors and gear (350 each)	2,450	4,900
Contingencies	1,070	1,540
	£21,000	£26,500
Annual Working Expenses.		
Coal, water, oil, &c.	660	1,100
Wages, including drivers	1,200	2,000
Maintenance channel and conductor, 5 per cent.	715	755
Maintenance cars (£70 each)	490	980
Maintenance steam plant, 7½ per cent.	165	265
Maintenance electric plant, 10 per cent.	100	150
Stores	200	300
Supervision and general expenses	470	650
	£4,000	£6,200

COPPER STEAM PIPES FOR MODERN HIGH-PRESSURE ENGINES.*

(Concluded from page 144.)

A burnisher or planisher, composed of a small square piece of agate, being the hardest and smoothest substance suitable and available, is supported upon proper arms and levers, and the agate is allowed to press lightly upon the surface of the copper on the revolving mandrel. The burnisher is caused to traverse from end to end of the mandrel by means of a leading screw at any required speed. After it has traversed the whole length of the mandrel, it is automatically reversed, and commences its journey backwards. The speed of the revolving mandrel and the speed of the traversing burnisher is so adjusted or arranged that the whole surface of the copper is acted upon by the burnisher, the result being that every thin film of copper deposited upon the mandrel must be separately acted upon, burnished and compressed into a dense and cohesive sheet of pure copper possessing a great amount of tenacity and ductility, as will be seen from the results of the experiments and tests which I have made, and which will be referred to further on. The impurities or dross fall to the bottom of the tank in the form of mud, and when washed, dried, and smelted in a crucible, the gold, silver, &c., contained therein can be easily separated. In fact, during the operation of refining copper from the rough Chili bars, the finished article is automatically produced in the form of a pipe, and all the impurities are extracted and can be collected.

While I was present at the works of Mr. Elmore, the patentee of this process, four pipes were made. The mandrels had been revolving in the baths for about 170 hours, and the copper in this length of time had reached a thickness of ·198in. The pipes were taken off the mandrels in my presence, and the ends of the pipes cut off, so as to present a portion of the pipes acted upon by the burnisher. The remaining portion, or rough ends, showed the nodules, or rough copper, not acted upon by the burnisher, and was in a completely brittle condition.

It is well known that the structure of ordinary electro-deposited copper is purely crystalline, and easily disruptured under stress. The adjoining faces of the crystals, of which the whole mass is composed, appear under the microscope to be separated from each other, and have very slight cohesive power.

In order to show the effect of the burnisher upon the material, I have had the structure of specimens of pieces of copper magnified under a microscope and then photographed. One photo was taken from an ordinary piece of cast copper. A second was taken from a rolled bar of copper. The difference in these two structures is very perceptible, and plainly shows the effect of work in the shape of rolling. A third shows the structure of a piece of ordinary deposited copper not burnished, and a fourth shows the structure of a piece of copper one-third unburnished and two-thirds burnished. From these photos it can plainly be seen to what extent the crystals are reduced in size, and the cohesive power of the material increased.

To describe more in detail how the decomposition of the unrefined copper is effected, and how the deposit takes place, I may state that the unrefined Chili bars are cast into slabs of the required length of the pipe, and these are arranged longitudinally in a wooden tank, in such a manner that the faces of the slabs are approximately at equal distances from, and parallel with, the surface of the cylindrical mandrel, both at its sides and underneath it, leaving the upper side open for the burnisher to travel over. The mandrel is fitted with a properly insulated spindle, running in insulated bearings, and driven by suitable wheel gearing, &c. The whole of this arrangement is immersed, as before stated, in a bath of sulphate of copper. The mandrel forms what is termed the cathode, and the copper bars the anode, of the electric circuit. The cathode is connected with the negative pole of an ordinary dynamo machine, and the anode with the positive pole. When the dynamo is set in motion, an electric current passes through the solution, and the following chemical changes take place. The sulphate of copper is decomposed, and the sulphuric acid is transmitted to the anode, there to attack and dissolve or combine with a quantity of copper equal to that which has been liberated or deposited upon the cathode.

The electric terms used in this matter of the deposition of copper are like those for electroplating and electrotyping, and it may be as well to describe them here.

1. The terms "cathode" and "anode" are synonymous with the positive and negative poles of an electric or galvanic battery.

Then to measure the volume of electricity passed between these points the term "amperes" is used as the unit, like feet or cubic feet, for measuring in the usual mechanical sense.

2. Then for expressing the force with which the volume of electricity is propelled the term "volt" is used as the unit.

3. The resistance opposed to the electricity is measured by "ohms."

4. The work done in the electrical circuit is expressed by "watts," in the same way that in a steam-engine the power developed is expressed by h.p. To put this shortly:

$$1 \text{ ampere} \times 1 \text{ volt} = 1 \text{ watt.}$$
$$1 \text{ watt} \times 746 = 1 \text{ e.h.p.}$$

These are the electrical terms employed by common consent in all European languages in connection with this science, and there are certain facts in relation thereto that are quite accepted.

The principal one to be noted here is that one ampere of electrical current will deposit ·005084 grains of copper per second per square foot of surface in a suitable bath and under fair circumstances. At the time I had the pleasure of witnessing the tubes being manufactured, the amperes and volts were measured by Siemens's standard instruments, from which, on the above basis, the quantity of copper electrically deposited in a given number of hours could be estimated.

In this way it was easy enough to judge of the horse-power transmitted through the dynamo to deposit a given quantity of copper or a given thickness of copper pipe of a given diameter. As to quality, it was by the nature of the process almost bound to be uniform; but in this respect the photos of the magnified pieces of copper, both before and after the burnisher has been applied, and the mechanical tests I have made are the best proofs. I may describe the latter as follows:—

Two of the four pipes I witnessed being manufactured I brought to London. One of these pipes I had fitted with strong flanges properly secured in an apparatus especially made for the purpose, and tested to destruction. The other pipe I had cut into two pieces, and one of these pieces I have kept and marked A. The other piece was cut and flattened out into a sheet, from which six test-pieces were cut and prepared for making tensile tests. I also obtained from Messrs. J. Wilkes and Sons, of Birmingham, two solid-drawn copper pipes of similar dimensions, and had them cut and tested in a like manner. The piece kept is marked B.

In addition to these pipes, I obtained from Messrs. Clelland and Thornburn, the well-known coppersmiths, of Glasgow, a brazed pipe of the same dimensions, made especially for my experiments, which was also tested to destruction, together with a sheet of best rolled copper, so that corresponding test-pieces could be made to those made from the electro-deposited pipe and the solid drawn pipe.

The results of these mechanical experiments are most interesting.

Pipe A, electro-deposited, stood a pressure of 3,450lb. per square inch before it burst. The material stretched and the pipe expanded uniformly until the copper was reduced in thickness from $\frac{3}{16}$in. to $\frac{1}{16}$in.

Pipe B, solid drawn, stood at a pressure of 2,200lb. per square inch. It also expanded, but not with the same uniform character as pipe A.

Pipe C, brazed from sheet copper, also stood a pressure of 2,200lb. per square inch, and burst, as all brazed pipes do, near the line of brazing.

The tensile strength and ductility of the copper cut from pipe A is given in the following Table.

* Paper read at the thirtieth session of the Institution of Naval Architects at Glasgow, July 25, 1888, by Mr. W. Parker, chief engineer surveyor to Lloyd's Register of British and Foreign Shipping, member of council.

TABLE A.—*Deposited Copper.*

Marks on Specimen.	Dimensions in Inches.			Tensile Strain in Tons.		Elongation per Cent.		Contraction of Area per Cent.	Remarks.
	Breadth.	Thickness.	Area.	Total.	Per Square Inch.	In 8in.	In 5in.		
A 1.	2·0	·175	·351	8·36	23·80	13·7	20·0	73	Electro-deposited copper, cut circumferentially from the pipe.
A 2.	2·0	·18	·36	8·36	23·22	13·0	17·5	68½	
A 5.	1 0	·18	·18	4·32	24·00	12·9	16·0	82	Cut longitudinally with the pipe.
A 6.	1·0	·18	·18	4·27	23·70	13·2	13·2	71	

It will be seen from these tables that the tenacity in the normal state of these three descriptions of copper—the electro-deposited, the solid drawn, and the rolled sheet—are 23¾, 20¼, and 14 tons per square inch respectively.

The very superior ductility of the pure electro-deposited copper is clearly shown by the manner of breaking, the elongation being chiefly confined to the neighbourhood of the fracture; and whereas the contraction of area at the fracture in the solid drawn copper is 12·8 per cent., and in the sheet copper 45 per cent., in the deposited copper it averages 72 per cent.

The tensile strength and ductility of the copper cut from pipe B is given in the following table:—

TABLE B.—*Solid Drawn Copper.*

Marks on Specimen.	Dimensions in Inches.			Tensile Strain in Tons.		Elongation per Cent.		Contraction of Area per Cent.	Remarks.
	Breadth.	Thickness.	Area.	Total.	Per Square Inch.	In 8in.	In 5in.		
B 1.	2·0	·195	·39	8·0	20·5	3·75	7·1	12·8	Solid drawn copper cut circumferentially from the pipe.
B 2.	2·0	·195	·39	8·0	20·5	3·75	6·9	12·8	
B 5.	1·0	·190	·19	3·8	20·0	2·90	7·0	43·6	Cut longitudinally from the pipe.
B 6.	1·0	·190	·19	3·8	20·0	3·10	7·0	36·8	

The tensile strength and ductility of copper cut from sheet copper, such as would be supplied for making pipe C, is given in the following table:—

TABLE C.—*Rolled Sheet Copper.*

Marks on Specimen.	Dimensions in Inches.			Tensile Strain in Tons.		Elongation per Cent.		Contraction of Area per Cent.	Remarks.
	Breadth.	Thickness.	Area.	Total.	Per Square Inch.	In 8in.	In 5in.		
C 1	2·0	·265	·53	7·46	14·0	45·0	50·0	44·5	Rolled sheet copper cut in the direction in which it was rolled.
C 2	2·0	·265	·53	7·46	14·0	44·0	50·0	45·5	
C 5	1·0	·265	·265	3·72	14·0	45·0	55·5	31·0	Cut across the direction in which it was rolled.
C 6	1·0	·265	·265	3·71	14·0	42·0	53·5	31·5	

The tenacities shown by the test-pieces are confirmed by the pressures at which the electro-deposited and solid-drawn pipes burst under hydraulic pressure, and, as before stated, the uniformity of the deposited material is very conspicuous.

In order to ascertain how deposited copper behaves as compared with solid drawn and ordinary sheet copper, and how its strength and ductile properties are affected by the action of heat, such as is contained in steam pressures that are now common, I have had a series of experiments made, the results of which are given in Table D.

The specimens were immersed in an oil bath while they were in the testing machine, the temperature of the oil being maintained by a gas flame; and by this means the specimens were pulled asunder at the temperatures given, which correspond with the temperature of steam at 200lb. pressure.

TABLE D.—*Table showing Effect of Temperature in Different Descriptions of Copper.*

Mark on Specimen.	Thickness.	Breadth.	Area.	Total Load in Tons.	Tons per sq. inch.	Percentage of Loss.	Temperature.	Remarks.
						p.c.	deg. F.	
P 1 ...	...	...	...	...	...	...	60	Cold.
P 2 ...	·237	2·0	·474	6·80	14·33	...	60	,,
P 3 ...	·237	2·0	·474	5·05	10·66	26	390	Rolled sheet copper.
			474	5·00	10·55	26	390	
S 1 ...	...	...	...	...	...	...	60	Cold.
S 2 ...	·192	2·0	·384	7·70	20·0	...	60	,,
S 3 ...	·195	2·0	·390	5·55	14·33	25·2	390	Solid drawn copper.
	·194	2·0	·388	6·10	15·7	...	390	
T 1 ...	...	...	...	...	24·0	...	60	Cold.
T 2 ...	·179	2·0	·358	5·50	15·35	...	390	
T 3 ...	·179	2·0	·358	5·25	14·65	...	390	Electro-deposited copper.
	·179	2·0	·358	5.45	15·2	...	390	

The results of these experiments are embodied in the preceding table, and are very interesting. The electro-deposited copper, it will be seen, as well as the solid drawn copper, stood about 15 tons per square inch, while cold rolled sheet copper broke at about 10½ tons, at the temperature of 390deg. Fahr.

Comparing these tests with the interesting series made by Dr. Kirk at Lancefield, to which I have before referred, and published in *Engineering* in December, 1887, I find there were twenty-three specimens of copper plates tested at the same temperature—viz., 390deg. Some of these were cut across brazed joints, and others clear of the brazing.

Of the nine samples which had been cut across the brazed joint, the mean tensile strength per square inch was 10·53 tons; but they varied in strength from 8·59 tons up to 12·32, or about 40 per cent., say, 20 per cent. above, and 20 per cent. below the average.

The fourteen samples that were cut clear of the brazing broke with a mean tensile strength of 11·81 tons per square inch, the variation ranging from 10·19 tons to 13 tons per square inch, or from about 10 per cent. above to 10 per cent. below the average.

Similarly comparing with the experiments made by me at the time of the "Elbe" explosion, the mean of four samples of sheet copper, at temperatures varying from 300deg. to 370deg. Fahr., was 9·93 tons.

Other experiments also go to show that ordinary sheet copper cannot be accorded a breaking strain of more than about 10 tons per square inch at the temperature of high-pressure steam, apart from the danger and uncertainty arising from brazing, which was so disastrously exemplified in the case of the "Elbe" and also the s.s. "Lahn." In the case of the electro-deposited copper, as also in solid drawn copper pipes, these experiments indicate a breaking strain at these temperatures of about 15 tons per square inch, or an increase of 50 per cent., and an absolute freedom from the dangers of brazing. This is a step in advance for which I am sure marine engineers will be grateful, and it comes none too soon, for our increasing high pressures have here discovered a weakness and danger that was bound to cause anxiety.

I find solid drawn pipes are now being made of larger diameter than hitherto, and I am not aware what the limit of their process of manufacture can go to; at any rate, there is no limit to which the diameters of the electro-deposited pipes can be made. Many other advantages are claimed for these electro-deposited pipes, which I have not investigated, but so far as steam pipes are concerned, it is obvious that absolute uniformity of density, thickness, and tensile strength, and true circular section (all of which are important qualities), can be obtained.

It is also established that copper deposited under a burnisher can be varied in tensile strength from the ordinary granular form to a material having high tenacity, and as it obviates the necessity for the steam pipes being

Digitized by Google

put into the fire for brazing purposes, the strength and safety at high steam temperatures may be still further increased, and if so, we shall, I am sure, be further gratified.

I cannot conclude this paper, which I hope may not be without interest to the members of this institution, and to others engaged in the manufacture and use of copper pipes, without expressing my thanks to Messrs. Maudslay, Sons, and Field for the great assistance they have been to me in carrying out a number of experiments, notably the bursting of the pipes, for which special appliances had to be devised, as also for the experiments at high temperatures. My thanks are also due to the Leeds Forge Company, who placed their testing machines at my disposal, and others who supplied me with copper and the necessary assistance and appliances for conducting these investigations.

MR. BROWN AND THE DOG.

The following ballad is suggested by the proceedings at Columbia College, July 30, 1888 :—

Then Brown he read a paper, and he demonstrated there
That alternating arguments were exceedingly unfair.
No company employed him, and his motives, he felt sure,
Were thoroughly unbiassed, philanthropic, and most pure.

He had read with deepest feeling that lives were sacrificed,
And in order to prevent this, new rules he had devised.
At once, as he expected, there arose a fearful din ;
And the alternating advocates hurled weighty papers in.

He took refuge in Virginia, until the sky was clear,
And, after slaying sundry dogs, he shouted, "I am here."
He was a most persistent man, this modest Mr. Brown,
And laboured every night and day to save our mighty town.

To prove that he was honest, his "plant" was all in view,
And he called out from the audience three men, all good and true.
One man was set to measure ohms, another watched the volts,
The third to watch the other two, and carefully take notes.

The dog stood in the latticed box,
The wires around him led ;
He knew not that electric shocks
So soon would strike him dead.

"One hundred volts we'll give him now,"
The dog did not despair ;
Brown wiped the sweat from off his brow ;
The dog turned not a hair.

"Two hundred more," then Brown, he cried,
The dog did not complain ;
He knew not that his friends had died,—
That he must die in vain.

At last there came a deadly bolt ;
The dog, O where was he!
Three hundred alternating volts
Had burst his visceræ.

EPITAPH.

Every dog must have his day ;
He had his and passed away.
He never drained life's bitter cup,
Death took him when he was a pup.

LEAMINGTON.

At the last Council meeting a long discussion took place, and the following letter was read on the question of the electric lighting of the town, respecting which there has been so much public discussion both in the Council and in the press: "Midland Electric and Power Company (Limited), Leamington. July 31, 1888. To the Town Clerk, Leamington. Dear Sir,—We beg to acknowledge receipt of your favour of the 10th inst., informing us that our letter of the 21st ult. was considered by the Council, and that they have given permission for the erection of four arc lights, by way of an experiment (provided no charge be made on the Corporation), on some spot to be agreed upon, at a height not exceeding 50ft., but that the Council object to the lights being placed on the Town Hall tower, as they considered the access undesirable, and the height (100ft.) far too great, and believe that a position facing the Parade would be more suitable. The essence of our offer was that the arcs should be placed on the tower, and therefore in a position not absolutely facing the Parade, should be at least 100ft. high, and, though lent and fixed by us free of charge, should be connected to the present mains, and the current, therefore, paid for by the Corporation. We may take it, then, that the Council have given us permission to do as nearly as possible the exact opposite of what we offered to do. We do not call in question the wisdom of the Council in wishing to try the effects of four arc lamps of 2,000 c.p. each, placed not more than 50ft. high, and facing the Parade, which at its narrowest point is only 50ft. wide. We only say that we do not wish to try this particular effect a second time at our own expense. We have already, at our own expense and on our own property, tried the effect of arcs between 30ft. and 50ft. high for street lighting. There is no mistake about the light. Used as we have shown it in Wise-street, it would take the place of ten street lamps. If the Council had not given attention to this particular illustration of the power of electricity as an illuminant, they can see it any night from nine till eleven. But this is an illustration of street-lighting by arcs. What we last offered to do was to give the town an opportunity of seeing street-lighting by incandescent lamps in combination with arc lighting of open spaces. The two are quite different problems. We think it extraordinary that so substantial and extensive a building as the Town Hall tower should only be available for the purpose of housing a clock, and we cannot understand how the man who attends to the arcs can do more damage to it than he who attends to the clock ; but we accept the decision of the Council, and now withdraw our offer, and we take the opportunity to withdraw also—at all events for the present—our former offer, made some three months ago, to bear half the cost of removing the arms that now suspend the 16-c.p. lamps from the posts and to exchange them for upright lanterns and 32-c.p. lamps. Our reasons are these : We find that our motives are not appreciated. We are supposed to be madly desirous for a continuance, at any cost, of our present contract for lighting the Parade, whereas, as a matter of business, we don't care about lighting the Parade at all. As far as the Parade is concerned, our chief desire was to assist the more public-spirited members of the Council in bringing Leamington abreast of the times. The system of lighting recommended by us, we admit, was discussed in full conclave and adopted unanimously, does not appear when in practice to please the Council ; this is a matter of taste and not of electrical engineering. Still we were willing to assist the Council in any change they desire ; but every offer we make is used by our opponents as the excuse for some attack on our reputation, and some fresh outpourings of local spite and local prejudice. When we have been personally present we have had no reason to complain of the result of the discussion ; but behind our backs the matter is different. There, statements are made to our disadvantage that are unsupported by any evidence that would be received in a court of justice, and that are untrue in fact ; and no effort is made to distinguish between legitimate criticism of matters of taste and opinion, such as the method of distributing the light and the appliances by which it is distributed, and for which matters the Council are now alone responsible. The other matters for which only we are responsible — the candle-power of the lamps—we ask (and surely it is not an unreasonable request) as a condition precedent of any fresh offer on our part that the candle-power of our lamps—should be regularly tested and published at the same time and in the same way as candle-power of the gas lamps is tested and published. As we noticed that the last one-sided discussion on the electric light which appeared in the papers was unaccompanied by our letter which gave rise to it, we shall feel obliged if on the present occasion you will hand this letter to the public press after it has been communicated to the Council.—Yours truly (for the Midland Electric Light and Power Company, Limited), ARTHUR CHAMBERLAIN."

The **Town Clerk** explained the reason why the company's letter had not been read at the Council meeting, was that it was addressed to Alderman Wackrill, and therefore went to the committee of which that gentleman was chairman.

Dr. Hardley-Wilmot hoped that the letter would be published in order that the ratepayers might see how the company treated the Council.

Councillor Crowther Davies said that he should have much pleasure in moving that the interesting document just read be referred to the Watch Committee. He regretted very much indeed the terms of the letter, and as a matter of taste he regretted that it had ever been written.

Councillor Harvey seconded the motion.

Alderman Wackrill thought it would have been better to leave the letter in the hands of the town clerk.

The **Mayor** said he regretted with Mr. Davies that such a communication had been sent to the Council, and hoped that before the company wrote letters again they would take the advice of a sensible man. Their correspondence was conducted in a most foolish manner, and he was surprised that Mr. Chamberlain should have sent them such a letter. The whole question would have to be discussed by the Watch Committee.

Councillor Barter-White thought the letter should be deferred until Councillor Davies' motion came on.

The matter was, however, referred to the Watch Committee in accordance with Councillor Davies' motion.

At the close of the ordinary business the Council proceeded to consider the only notice of motion on the agenda paper, which had been placed there by Councillor Crowther Davies, and was in the following terms : "That the town clerk be instructed to give forthwith on behalf of the Corporation twelve months notice (under clause 4 of the agreement dated the 10th day of August, 1887, and made between the Midland Electric Light and Power Company, Limited, of the one part, and the mayor, aldermen, and burgesses of the borough of Royal Leamington Spa of the other part) to determine the supply of the electric light."

Councillor Crowther Davies said : I respectfully ask leave from yourself and the members of this Council to withdraw this resolution, which has just been read by the clerk, and which stands in my name. And I ask further, sir, the kind indulgence of the Council while I, in a very few words mention my reasons for that withdrawal which, I think, as a matter of respect to the Council, I ought to give. I wish, and I am sure we are all of one mind in this matter, to leave no means whatever untried whereby an accommodation may be found as between this Council and the Electric Light and Power Company. Several members of this Council have intimated to me that, anxious as they are that this notice should be given, supposing all means have failed whereby any negotiations are likely to be satisfactorily con-

Digitized by Google

cluded, yet they desire, and I am perfectly with them in their desire, that the company shall not be able in any shape or way to say that any hasty step has been taken by this Council to put an end to the contract, but that, on the contrary, they wish that every means should be used to bring about a satisfactory state of things, and one which will allow all means to be taken to make Messrs. Chamberlain and Hookham's venture in the town a successful one, and one that would redound to their credit as electricians, and to the satisfaction of the ratepayers of the borough in providing them with a brilliant, and an economical, and a real electric light. A letter has been read to-night to this Council from Mr. Chamberlain. I wish to say no harsh words about that letter. I wish merely to say this, that it is undoubtedly a most unfortunate one, but unfortunate only for the writer of it, and not for its recipients. (**Councillor Johnson:** It is a very rude letter.) Mr. Chamberlain has formed a most unjust and unworthy conception of this Council as a whole, and of some—if I may be permitted to say so—of its individual members. Perhaps, if this resolution is withdrawn, which I, sir—and Mr. Chamberlain might know if he were in this room—could carry if I willed, perhaps Mr. Chamberlain will come to the conclusion himself, that he would do well to treat us as reasonable men, as just men, and as honourable men, and as desiring by no means to throw cold water on his company, but trusting that he and his company may see fit so to meet us that we, with due regard to the interests of the ratepayers, may also meet them. I hope if this resolution be deferred for a period, Mr. Chamberlain may be found amenable to reason. His forte, whatever it may be with regard to electricity, does not at any rate extend to the writing of letters. If he will see us, or you—if he will see those to whom this matter may be deputed, and act as a reasonable man—he will have no cause of complaint, I am quite sure, of any treatment of ours in the future. I ask respectfully the leave of the Council to withdraw this resolution.

Councillor Bright: I beg to second that proposal, and to compliment Mr. Davies on the conciliatory way in which he has treated this subject. It is the more generous, as it is patent to all of us that there is in this room at this time a majority of the gentlemen who formerly voted for that resolution. Mr. Davies is consequently quite right in saying that if he chose to press this motion he might carry it; and I certainly compliment him that, having that in his power, he treats the question, as he has done, in such a gentlemanly way. It is the more generous, because he must have felt, as a great many of us feel, the sting of that extremely unwise letter read by the town clerk. I hope that it will not be thought by those gentlemen either that we have been affected by that letter, or that we are satisfied with what they have given us in the way of electric light. As one of the promoters of that light, I say myself that they have not given us that light that we, as a Council, ought to accept for the town. I have no hesitation in saying that when I voted for the introduction of the light—and I believe I was the proposer of the motion—into Leamington streets, I did not vote for such an extraordinary illumination as they have given to us. The fault is not in the electric current, I am satisfied, although when first laid down, as it happens often with new installations, the fault frequently did lie with the current. That has been remedied, and the fault now lies in the lanterns, which I say, according to the contract, are not our property, but the property of the Electric Lighting Company. The standards are put, some in one direction and some in another direction. The standards as a pattern are according to a plan which was deposited with this Council, and in reference to them we are responsible as well as they for the ugly structures we have now. But the lanterns we are not responsible for. They are provided by the Electric Light Company, and I say that by Clause 5 in their contract they are to remain their property. I believe—and I should not say it if I did not believe it—that with a very trifling alteration we can make this installation perfectly satisfactory to us, and perfectly satisfactory to the ratepayers of Leamington. I feel sure that the incandescent light can be made—and with very little cost—to give such a diffusion of light in our streets as would be infinitely superior to gas, and at no greater cost. But that is not the case with the lanterns supplied by Messrs. Chamberlain. Part of these have metal tops and reflectors. You go a yard or two and there is another with a porcelain top. No installation, and especially an installation for a town of the importance of Leamington, ought to be of this magpie order—one one pattern and another another, one in one direction pointing north, another east, and another south, so that looking up the street from the bottom you see a sort of wavy line of little lights, some of them much brighter than others, inasmuch as those with porcelain tops allowed the light to pass through them while the metal tops obstructed it.

The **Mayor**, interrupting Councillor Bright, said that as Councillor Davies wished to withdraw the resolution, he could not allow any discussion.

Councillor Bright: I am seconding the withdrawal of the motion.

The **Mayor:** It is unnecessary to have a seconder.

Councillor Bright: I bow to your decision, sir.

Councillor Purser remarked that he thought it was unfair, having had speeches on one side, not to hear those on the other.

Councillor Davies said that, supposing after the interval of a month or two no means of accommodation were found between the Council and the company, he should consider it his duty to renew the resolution. He did not want the ratepayers to think he had in any way retreated from his former position. He wished to be more than fair to the company, but he did not intend to allow the matter to go on indefinitely.

The Council agreed to the withdrawal of the resolution, and the **Mayor** suggested that the whole question be referred to a committee of the whole Council for full discussion.

Alderman Gilbert proposed that the matter be referred to a committee of the whole Council, and that Messrs. Chamberlain and Hookham be asked to meet them and confer with them on the subject during the ensuing month.

The **Mayor** suggested that the committee should first discuss the question, and having arrived at some decision should consult Messrs. Chamberlain and Hookham afterwards. A feeling of irritation had very naturally been caused amongst the members of the Council as business men by Mr. Arthur Chamberlain's letter, and he thought it would be better to defer the consultation with the company until all that feeling had passed away.

Alderman Gilbert amended his motion as suggested by the Mayor, and it was then seconded by **Alderman Wackrill,** who advised that the letter should also come before the committee.

Councillor Purser remarked that he should like to add that the speeches which had led up to that letter be also considered. If they had had three months ago such conciliatory speeches as they had heard that day, he felt convinced that they would never have had such a letter from Mr. Chamberlain. That letter was only the result of speeches delivered there formerly, which he had been very sorry to hear. He did not know what the majority in favour of Mr. Davies' motion was. He supposed someone had been round and got to know the opinions of the members of the Council. He did not know how members would have voted, but he supposed someone else knew. He hoped the question would be dealt with on its merits when it came before the General Purposes Committee.

Councillor Davies remarked that as to the previous speeches on the subject, if they had been untrue, no doubt they would have been exposed ere that time. He stuck to every word he had said about the electric light, and was prepared to substantiate it. He was not in the habit of saying one thing one day and backing out of it the next. He must say he thought it was invidious to speak of past speeches when the desire had been shown by Councillor Bright and himself to place the matter in such a position that it could be calmly and properly discussed in such a temper which would become and benefit the subject and both parties interested. With regard to the letter, for his own part he should have ignored it, and have put it behind the fire, and have forgotten it. Of course, if the Council wished to keep the letter in its archives as a specimen of what an irritable and foolish man could write, by all means let them do so.

Alderman Gilbert's motion, that the matter be referred to a committee of the whole Council for discussion, was carried, and it was agreed that the meeting should be held at an early date.

Councillor Purser moved that the Lighting Committee take means to ascertain the amount of light given by the electric lamps in the streets.

The **Mayor** suggested that that resolution, which dealt with a very important matter, should be considered by the committee of the whole Council when they went into the whole question.

Councillor Barter-White: I object to its being adopted now.

The **Mayor:** You can't object now. It will be a matter for the Corporation to vote upon.

Councillor Bright asked the surveyor if he had any apparatus by which he could test the electric light if it was fitted up.

The **Surveyor** replied that there was an apparatus which, at a cost from £10 to £12, could be fitted up to test the electric light.

Councillor Salmon seconded Councillor Purser's motion, and remarked that he thought they ought to get to know all they could about the light, and that some steps should be taken to have it tested, even although it might vary. They would be able to arrive at a better estimate of what the light really was by having it tested.

Councillor Davies asked why they could not meet on a common ground. It had been proposed to the Company that they should furnish a test, and they instantly refused to do anything of the kind. But what sort of test did they propose to have. Did Councillor Purser delude himself with the notion that the test applicable to gas was also applicable to the electric light? A gas test showed the quality of the whole volume of gas at that time in the gasometer, but as to the electric lamps he could take Councillor Purser to one lamp and have it tested, and it might register 20 c.p., and he would take him ten minutes after, and he would find it had very considerably diminished. Any such test would, therefore, be utterly fallacious.

The **Surveyor,** who was appealed to by **Councillor Davies,** confirmed his statement with regard to the test.

Councillor Purser said he had never mentioned a gas tester at all. He wanted to know the average light of the whole lamps on the Parade, and to see whether they were under or over the power contracted for.

The resolution was lost by six votes to three.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The traffic receipts of the Brazilian Submarine Telegraph Company, Limited, for the week ended August 17, 1888, amounted to £4,596.

Western and Brazilian Telegraph Company. — The traffic receipts of the Western and Brazilian Company for the past week, after deducting the "fifth" of the gross receipts payable to the London Platino Brazilian Company, were £3,813.

West India and Panama Telegraph Company.—The estimated traffic receipts of the West India and Panama Telegraph Company, Limited, for the half month ended 15th inst. are £2,533, as compared with £2,048 in the corresponding period last year, showing an increase of £485.

West Coast of America Telegraph Company.—At the usual meeting of the Directors of the West Coast of America Telegraph Company, Limited, Mr. Frederick Walters, of 12, Tokenhouse-yard, E.C., and partner of Messrs. Huth and Co., in Valparaiso, was elected to a seat at the Board.

PROVISIONAL PATENTS, 1888.

AUGUST 10.

11,529. **Improvements in electric lighting.** William Towle, Midland Grand Hotel, St. Pancras, London, and William Edward Langdon, Midland Railway, Derby.

11,544. **Improvements in electrical coinfreed machines.** James Gilbert Cumming, 7, Union-street, Edinburgh.

11,561. **Improvements in gas incandescent lamps.** Edmund Ritter Klein von Ehrenwalten and Carl Fabricius, 28, Southampton-buildings, London, W.C.

11,568. **Improvements in electric batteries.** William Shedlock, 45, Southampton-buildings, London.

11,569. **Improvements in secondary and other electric batteries.** Henri Pieper, 47, Lincoln's-inn-fields, London, W.C.

11,570. **Improvements in electric arc lamps.** Henry Pieper, Fils, 47, Lincoln's-inn-fields, London, W.C.

11,573. **Improvements in electric lamps.** Henry Head and Llewellyn Saunderson, 24, Southampton-buildings, London, W.C.

AUGUST 11.

11,582. **Improvements in apparatus for the electro-deposition of metals and for the separation of chemical compounds or bases therefrom.** Frederick Henry Varley, 2, Victoria Mansions, Westminster, S.W.

AUGUST 13.

11,681. **Improvements relating to electric batteries and to exciting liquids or compounds therefor.** E. Liebert and Sally Adolf Rosenthal, 45, Southampton-buildings, London. (Complete specification.)

AUGUST 14.

11,703. **Improvements in electric dynamos and motors.** Edward Crowe, Grove Hill, Middlesbrough-on-Tees.

11,705. **Improvements in apparatus for measuring electric currents, and recording the amount of electric energy consumed in a given circuit.** William Phillips Thompson, 6, Lord-street, Liverpool. (The Westinghouse Electric Co., United States.) (Complete specification.)

11,718. **An induction apparatus—a substitute for dynamo-electric machinery—for the generation of electricity, without converting the energy of mechanical motion into the energy of electric currents—i.e., without moving coils of wire past magnets or magnets past coils of wire.** Joseph Gozo, 41, George-street, Portman-square, London, W.

11,737. **Improvements in electric bell pushes.** Gustav Binswanger, 5, Gt. St. Thomas Apostle, London, E.C.

AUGUST 15.

11,749. **Improvements in the manufacture of carbons for electric lamps.** John Scudamore Sellon, 47, Lincoln's-inn-fields, London.

11,766. **An improved electro-ozone producing apparatus.** Francis James, 45, Southampton-buildings, London.

11,779. **Improvements in galvanometers.** Edouard Emmanuel de Facieu, 33, Chancery-lane, London. (Complete specification.)

11,782. **Means for disengaging the regulating mechanism of electric arc lamps and clockworks which disengage by electricity.** Eduard Correns, 89, Chancery-lane, London, W.C.

AUGUST 16.

11,798. **Improvements in fittings for electric bells.** William Woodall, trading as James Macintyre and Co., 23, Southampton-buildings, Middlesex.

11,809. **Improvements in electrometers and apparatus for measuring the electric potential of the earth and of its atmosphere, and of any other body or gas.** Arthur Hill Maurice, Lacelles Carr, and Daniel Owen, Cardiff, Glamorganshire.

11,817. **Improvements in electric furnaces.** John Covert Hobbs, Cleveland, Ohio, Cuyahoga, United States. (Complete specification.)

11,858. **Improvements in electric batteries.** Owen Charles Dalhousie Ross, 8, Quality-court, W.C.

COMPLETE SPECIFICATIONS ACCEPTED.

OCTOBER 10, 1887.

13,720. **Apparatus for effecting electrical measurements and contacts.** Achilles de Khotinsky, 28, Southampton-buildings, Chancery-lane, London, W.C.

NOVEMBER 11, 1887.

15,455. **Apparatus for connecting a number of separate electrical conductors to one main conductor.** William Snow Rogers, 28, Southampton-buildings, Chancery-lane, London, W.C.

JANUARY 17, 1888.

713. **Improvements in voltaic or galvanic batteries.** Theophilus Coad, 10, Thorpe-terrace, Thorpe-road, Forest Gate.

MAY 24, 1888.

7619. **Primary electric battery.** George James Weir, 22, Renfield-street, Glasgow.

SPECIFICATIONS PUBLISHED.

1887.

10,131. **Meters for electricity.** G. Forbes. 8d.

10,157. **Transmitting, &c., electrical signals.** T. A. Garrett. 8d.

11,252. **Secondary batteries.** H. Mower. 8d.

11,901. **Lamp holders for incandescence electric lamps.** R. A. Scott. 8d.

12,015. **Incandescent electric lamps.** W. Löndholdt. 8d.

12,683. **Spongy lead for electrical accumulators.** F. M. A. Laurent-Cely. 8d.

12,718. **Electrical speed indicators.** J. Tate. 8d.

1888.

4221. **Holders for incandescent electric lamps.** T. Coad. 6d.

7852. **Electric distribution.** (Westinghouse, jun.) 8d.

NOTES.

Washington.—The House, at Washington, has appointed a special electrical engineer to make plans for lighting and to solicit tenders.

Harold P. Brown and the Dog.—The poetry on this subject, which appeared in our last issue, should have been credited to the *Electrical Engineer*, of New York.

Four Virtues.—The electric motor, says one user of them, is (1) clean, (2) noiseless, (3) compact, and (4) cheap. This is the sort of character for a go-ahead article.

Electric Light Posts Wanted.—Mr. Massingham wants 240 iron posts for his Bath lighting scheme. Particulars can be found in our advertisement columns.

Who Invented Electric Welding?—Dr. Otto Moses, of New York, is contesting Prof. Elihu Thomson's claim as the inventor of electric welding in the New York courts.

Richmond, Va.—The Sprague Company are running an extra two miles of double track of electric road to carry passengers into the exhibition, commencing on October 3. The company have bought up the rival horse-car road, and will apply electricity to the whole system.

Dover.—At the last meeting of the Council a letter was read from Messrs. Laing, Wharton, and Down, asking the Council to consider the question of lighting the streets of Dover with the electric light, and the consideration of the question was adjourned for one month.

Saving Their Fuel.—The St. Lawrence Marble Company are anticipating making a saving of £1,000 a year in fuel by using the water power in the St. Lawrence by means of a dynamo and motors for driving the machinery at their quarries, at present driven by a 100 h.p. steam-engine.

Shocks from the Letter-Box.—In one town where electric light is used, a letter-box is attached to one of the poles. A lady who attempted to post a letter here was discouraged from further attempts by a very fair shock. A gentleman lifted the lid and pushed the letter in with his stick.

Dictionary of Electricity.—A work is announced by Prof. Houston, giving definitions of electrical words, terms and phrases. This should prove very interesting and useful. If French and German equivalents were given in addition, its usefulness in technical hands would be much increased.

Electrical Treatment of Sewage.—Iron seems to be the only material of practical value, according to Mr. Webster's experience, for positive electrodes in his treatment of sewage. He has therefore filed an amendment limiting the patent to the use of positive electrodes of iron, except in the case of the filtering process.

Rawdon.—The township of Rawdon, it appears, has no public lighting. A scheme of gas lighting last week was submitted to the Local Board, the cost to be about £2. 10s. each for 104 lamps, and the cost £1 each for maintenance per year; but the project was rejected. If anyone wishes to convince the Local Board of the benefit of electric light, now is the time to try it.

An Electrical Society for Japan.—Under the presidency of Viscount Enomotto, Minister of the Department of Communications in Japan, an electrical society has just been formed, and already numbers more than 800 members. The chairman of council is Mr. R. Shida, who is local honorary secretary of the Society of Telegraph Engineers and Electricians in Japan.

Train Lighting.—We notice that the Lancashire and Yorkshire Railway have not been able to determine upon the provision of the electric light for their travellers, and, after conducting some experiments with the electric light, have finally adopted a patent gas for their carriages. It is claimed that it is better and cheaper than oil lighting, and is more economical than electric light.

Its only Rival.—The only final rival to the Tesla motor is the Keeley one; that would beat it, if it would work. The Keeley Company have called upon Mr. Keeley officially to disclose his secret, or henceforth and for ever hold his peace. He offered to do this eighteen months ago, and now is compelled to do so, or fall. And he cannot do it. The Keeley "motor" won't "mote."

Gilchrist Engineering Scholarships.—An entrance scholarship will be offered at University College, London, in the month of September. The value is £35 per annum, tenable during two years, and the competition is limited to those who have not previously been students of the college, and who will not complete their nineteenth year before October 1. A senior scholarship of £80 will be awarded at the close of the session.

Motors on Arc Circuits.—The Baxter motors are worked successfully on arc circuits in the States without interfering with the steadiness of the light. There is no difficulty about it. Our pushing electrical engineers might note that arc or incandescent, alternating or direct, motors will now work on all circuits. They will hoist and ventilate, and turn lathes or heavy machinery. The motto for electrical managers should be: "Fill up the valley of the load diagram."

Electrical Thief-Catching.—A bit of neat thief-catching comes to us from St. Louis. There had been a considerable amount of petty thieving going on at one of the electric light stations, but the thief could not be caught. The following electrical remedy was tried. A large piece of brass was laid in the window-sill. This was connected to a 20-light circuit, known to be slightly grounded. In due time the thief arrived. He caught at the bait, and in less time than it takes to tell it he was landed in the centre of the street. Nothing has been missed since.

The "Great Eastern".—The poor old "Great Eastern"! She is to go to the knacker's yard at last, and is to be broken up and sold as old iron. First built with the idea of revolutionising the ocean trade, after an unsuccessful run she was utilised for cable-laying, and now, after having fallen to the *role* of a floating palace of varieties, and failing in this as in other functions, she is to be broken up and the machinery sold. Someone ought to have tried at getting up a company for using her machinery as a floating electric light station, and failed—with a large profit—and her misery and uselessness would have been then complete.

Cost of Telephone.—According to a series of statistics given by *La Cote Libre* of Brussels, the cost of telephones in France varies according to the length of the lines from £14 to £24; in Germany it is £10 for a line of two kilometres, with £2. 10s. added for each kilometre; in Austria it is from £10 to £15, in Belgium and Spain from £8 to £12,

Digitized by Google

in Italy £4. 12s. to £7, Norway from £4 to £8, Sweden £6. 8s. to £10. 16s., in Switzerland from £4 to £10, in Holland £10, in Luxemburg £3. 4s., and in Portugal £15 for merchants and £7 for individuals. In England the cost is £20, and in Russia £25. We are thus in the unenviable position of being last but one in the class.

Secured a Gold Mine.—"It is safe to say," says the *Pittsburgh Post*, "that the Westinghouse Electric Company has a gold mine in its new electric motor. The public, even the electric public, has not yet reached a realisation of the importance of the invention. The motor was invented by Nikola Tesla, a native of Lika, a town on the border line of Austria and Hungary. He was educated in Austria, and graduated as a civil engineer. Electricity soon claimed his entire attention, and now, though apparently less than 30 years of age, he has a very wide reputation as an electrician. The Westinghouse has contracted for his patents on the new motor, and he has been in Pittsburgh several weeks proving all he claims for his invention."

Better than Candles.—"The King's palace has been urnished with Edison's electric light, which has been found better and more economical than candle and kerosene." This is an item of intelligence from our consul at Corea. We envy, says the *Daily News*, the Coreans their surprise on finding that candle-light, or even kerosene, could be eclipsed by modern methods of illumination, and felicitate Mr. Edison on the enlightening effect his incandescent carbons must have had upon a country which has only recently proposed to open itself up more freely to foreign commerce. Perhaps America and Europe may have a few more surprises in store for the Coreans if allowed to prepare them; while Corean products, which appear to be mainly gold, beans, and the medicinal root ginseng, would have their value as exchange.

Alexandria.—At a meeting of the Shipping Committee of the Hull Chamber of Commerce, Mr. J. Atkinson presiding, it was stated that the Khedive proposes to render Alexandria Harbour more available in stormy weather, as well as at night, by widening it 300ft., with a depth of 30ft.; and also lighting it with the electric light, on condition that the shipping trade will contribute for twelve years at the rate of 4½ to 5 paras per registered ton—which is equal to £1. 5s. 6d. for every ship of 1,000 tons register. It was eventually proposed by Captain Hedger, and seconded by Captain Hill, that the proposed facilities at Alexandria were such that it would be advantageous when the work had been completed for shippers to enter into arrangements such as those suggested in the communication received from the Khedive of Egypt.

Gratuitous.—"Mr. C. B. Harness will esteem it a favour if you will kindly insert this editorial in your next issue." With this request comes a printed slip and a lithograph letter, the former of which is the proposed editorial. Similar letters have, we presume, been freely distributed; at least, we have had the good—or bad—fortune to have received three separate copies of the circulars. It may save future trouble and expense to say that we have our own opinions about editorials, and we express our own opinions; we neither ask nor expect that opinions upon electrical questions shall be put into our mouths by parties interested in the sale of goods criticised in these columns editorially. There is a large class of people who buy goods because such goods are extensively advertised. We believe in advertising, but we also very strongly believe in having value for our money.

The Liverpool Company's Excursion. — On Saturday last the employés of the Liverpool Electric Supply Company, Limited, had their annual excursion, Blackpool, in this instance, being the rendezvous of the party. After two hours' preliminary examination of this interesting watering place, the company met at the Derby Hotel, where an excellent dinner was provided. At the conclusion of the dinner, Mr. B. N. Collins, the secretary, took the chair, and while commenting on the steady progress of the company's operations, referred to the improved outlook for electric lighting, not only in their own district of Liverpool, where it is already being well taken up, but throughout the country generally. Votes of thanks and congratulations were proposed to the managing directors, Messrs. Holmes and Vaudrey, seconded by Mr. A. Clough, the foreman, and enthusiastically received by those present. After several hours' further examination of the various interesting sights at Blackpool, finishing with a concert in the evening at the hotel, the party returned to Liverpool, having spent a most enjoyable day.

Transformer Patents in America.—The Westinghouse Company, having entered a suit to prevent the Sun Electric Company from using transformers under Gaulard and Gibbs' patents, the court has decided that the defendants, using a multiple arc transformer system, do not infringe the patent. The original patent covered all forms of converters. The Patent Office considered this too broad a patent, and instructed the applicants that they must conform the arrangement of converters to the series system, that being the arrangement shown in an article in *Engineering*, of March 2, 1883, which the applicants declared contained a description of their invention. A disclaimer was accordingly inserted. The court now holds that it is too late for the plaintiff to say that the disclaimer means nothing; that by the disclaimer Gaulard and Gibbs were expressly limited to the series system, and therefore that the defendants, who used the multiple arc system, do not infringe the patent. The court accordingly decided, without entering upon other defences raised, that the bill should be dismissed.

Miners' Lamps Ordered.—Mr. Rees has again exhibited his miners' lamp to the members of the Cardiff Exchange, and stated that the lamp had been thoroughly tested at Lewis's Merthyr Collieries, and that the manager, after this test, "strongly recommended it for colliery purposes as the best he had seen." This gentleman, in his letter to Mr. Rees, said "the mechanism is simple, the lamp is perfectly safe, the light under no circumstances coming in contact with the air or gas. It gives the amount of light you (Mr. Rees) states, and it burns without diminution of light, having also the great advantage, not possessed by any other lamp, of thoroughly lighting the roof." This letter was accompanied by a very substantial order to Mr. Rees to supply a number of his lamps for the Lewis's Merthyr Collieries. Other colliery proprietors, having examined the lamp, are satisfied with its action, but object to the price (30s.) as compared with 6s. of the usual lamp. Mr. Rees stated that, when tested at Lewis's Merthyr Collieries, one of his lamps gave light more than equal in power and brilliancy to that given by eight of the "Protected Cambrian" lamps placed in a line across a heading—a statement the accuracy of which was vouched for by Mr. J. L. Phillips.

Cheltenham.—The determination of the Bath authorities to adopt the electric light has led the Cheltenham

Digitized by Google

authorities to give considerable attention to the proposal to light their own town by the same means. The statement has appeared to the effect that it is intended to light the town with 36 arc lamps in place of the 170 present gas lamps at an annual cost of £444. This is the present price for gas lighting, and Mr. Denny Lane writes to point out that this statement is not correct. He says: "The present cost of the 170 gas lamps is £444, or £2. 12s. 3d. per lamp, and the committee suggest that the contractors who now supply 70 lamps to the Corporation of Bath at £18. 17s. 6d. per lamp, should be asked to supply 36 lamps to Cheltenham at the same rate per lamp, which would amount to £679. 10s., and not £444. I must remark that it is highly improbable that 36 lamps could be supplied at as low a rate as 70, since I believe there would be little difference in the skilled labour and attendance for either installation, which would have to be divided over only half the number of lamps at Cheltenham. I may add that it seems unfair to gas companies that corporations should have the power of contracting with them for only three years, while at Bath the contract for electricity extends to seven." It is stated that the authorities have decided to light a portion of Cheltenham with electric light.

High v. Low Tension.—The battle of the high and low tension systems is likely to wage very fiercely in New York when the Westinghouse Company gets fairly to work in that city. One of the first large central distributing stations for electric light was that of New York, where the Edison system was installed upon a large scale. The Westinghouse high tension transformer system has spread itself far and wide over the States, and now essays to compete for favour in that city on a scale commensurate with its necessities. A large station is now in progress, and the owners of the low tension system are becoming alarmed. The grand discussion upon the danger of high-tension alternating currents, and the experiments upon dogs to which we have alluded are to be taken as the outcome of attempts on the part of the low-tensionists to keep the lighting in their own hands by an appeal to the element of danger in the opposing system. The Westinghouse is no mean rival, and the Edison Company will have to get on their mettle to the utmost to hold against them. They have now over 100 central station plants successfully working, and have an advantage in the public eyes in their alternating current meter, which registers directly in lamp hours, and has a mechanical movement. The Westinghouse Company have now, also, a very great pull in their possession of the Tesla patents for alternating current motors, and there is no doubt a very sharp commercial battle will be waged. The station in progress is for 50,000 lamps.

Gas not Doomed.—"Whatever progress the electric light may be making, at all events it has not interfered with the progress of gas." Such were the words addressed by Mr. Edward Lawrence, chairman of the Liverpool United Gas Light Company, at the last meeting of the shareholders; and with good grounds for the assertion. In the year 1883 "B" stock of the company, when publicly sold, brought, on the average, £125. 8s. 10d.; in 1884, £131. 2s. 5d.; in 1885, £150. 6s. 6d., while recently £50,000 of that stock realized, on the average, £153. 5s. 1d. per cent. This continuous increase in the value of gas stock, thinks the *Gas World*, effectively answers those prophets who say that gas, as an agent for lighting, is doomed, and that electricity is the "light of the future." We may add our opinion to that of our gas contemporary that gas may not be doomed, and yet electricity may be the light of the future. Horses were doomed—by the prophets—when the steam-engine was introduced. Now more horses than ever are used, though horse travelling is not the usual method of rapid transit. It comes simply to this, that, as Emerson puts it, more can be bought for a dollar in one age or one country than in another where material progress is less developed. In Florida a dollar will buy you oranges galore, but not fifty miles an hour travelling, or cheap clothes. Gas will not be doomed, but the dollar will buy more and more of it in the future. It may be used for all and sundry purposes for which at the time it was invented as an illuminant it could not possibly have been utilised were the dollars brought in sacks, and the user been as full of wants as the importunate widow, simply for want of the material means of utilising. Cheer up, Mr. Gasman, your per cents. will be all right, but you had better leave the "light of the future" to us, after all.

Electrical Industries.—In a leader upon the extension of electrical industry, the *Globe* wonders how it is that electrical tramways have not attained a more extended use in England, remarking that the parliamentary difficulties experienced in electric lighting did not apply to electrical traction. It instances the telpher line at Glynde as being very successful in its action, and is surprised that the same system has not been adopted in other places where transport is difficult. What, it asks, have electrical engineers been doing during the last few years? and thinks it is not very far wrong in answering that they have been preparing and waiting for the good things coming. The Act of 1882 has certainly had a good effect in more than one way. It has prevented an immense amount of useless speculation in electrical matters, and it has given time to the electrical engineer to work out problems which were hardly given a passing thought six years ago. If electric lighting had come into general use, there is not the least doubt that there would have been some dreadful failures. We should have had "jerry" work in the wiring of houses, besides endless breakdowns in the generating station. The long interval during which the public has had to wait for the modern light has given time to train the men in their respective duties. Early in the year the president of the Society of Telegraph-Engineers said that about 5,000 persons are employed in London in manufacturing electric light machinery. What becomes of all this plant nobody seems to know. Of course large quantities are sent abroad, even new mining towns in South Africa being lit by electric light. Now that the new Bill has passed through Parliament and received the Royal assent, we may expect to see central stations established in all our large towns, and, indeed, where water-power is available, in our small towns too. The time has now come, adds the *Globe*, when we may expect to see electrical science advance with rapid strides, but the "mysterious fluid" burned such a hole in the investor's pocket in 1882 that it is no wonder progress has been retarded.

An Electric Mountain Railway.—A correspondent of the *Daily News* in Lucerne calls attention to the electric mountain railway—the first of its kind—which has recently been opened to the public at Burgenstock, near Lucerne, under the superintendence of Mr. Abt, the Swiss electrical engineer. A bed has been cut for the most

Digitized by Google

part out of the solid rock in the mountain side, from the shore of the Lake of Lucerne to the height of the Burgenstock — 1,330ft. above its level, and 2,860ft. above the level of the sea. The total length of the line is 938 metres, and after the first 400 metres a gradient of 58 per cent. is maintained for the rest of the journey. A single pair of rails is used throughout, with the exception of a few yards at half distance to permit the two cars to pass, although only one car is at present used. The motive power, electricity, is generated by two dynamos, each of 25 h.p., which are worked by a water-wheel of 125 h.p., erected upon the river Aar, at its mouth at Buochs, three miles away. The loss of electricity in transmission is estimated at 25 per cent. Only one man is required to manage the train, and the movement of the cars is completely under his control. One dynamo is sufficient to perform the work of hauling up and letting down the cars containing 50 or 60 persons. A finger moving along a figured disc before the man at the water-wheel enables him, by means of a millimetre screw, moving at the rate of a millimetre to every metre of the railway, to see the exact position on the line at any given moment of the journey, and he can increase or slacken speed accordingly. In addition to this advice, the cars themselves give him a signal at stated points, after leaving the stations, by ringing a bell at the machine-room. The most complete safeguards are used to prevent the cars breaking loose by means both of breaks and cog-wheels for ordinary use, and a steel anchor in case of accident, which will effectually prevent the car running backward. This interesting undertaking has been carried out at a cost of £25,000. The electric power gained at the stream by the water-wheel also lights the whole of the hotel buildings and its grounds by electricity, and when the railway is not working, another dynamo pumps up spring water 1,000ft. for use in the establishment. The prospect is almost equal to that from the Rigi, and the Burgenstock will, doubtless, henceforth claim a much greater share of attention than hitherto.

Colliery Lighting.—In the reports of Her Majesty's Inspectors of Mines, for 1887, on the subject of lighting collieries, Mr. Moore says: "The incandescent lamp is still progressing towards improvement. Lamps of this kind have been exhibited and tried, but they have not, so far, been adopted in any colliery here. If a practical lamp of this kind could be got, suitable for all mines, whether fiery or not, it would greatly minimise the accidents from fire-damp, because there would be no inducement to use, in any circumstance, any other lamp than a safety lamp, and small explosions would cease." Mr. Hall says: "A great change has taken place during the last two or three years with respect to the kinds of safety lamps used in mines. The old-fashioned Davy has been almost universally discarded, and lamps of a new type introduced, these latter being largely constructed of glass so as to obtain a better light, such as the Mueseler and Marsaut lamps, and are so shielded as to withstand high currents, but many practical men, more especially managers who have raised themselves from the ranks, hold the opinion very strongly that the increased use of glass without a protecting gauze in the new lamps will eventually prove a greater danger through accidental breakages than the danger that existed where unprotected Davys were in use, of the flame being passed through the gauze in high currents. This change, which is now imperative under the Act of 1887, has not been adopted with any great amount of confidence as to any beneficial result, because the best lamps in the market even now are far from ensuring any high degree of security. Electric lighting has made substantial progress, and at two or three mines here installations of fixed lights on the surface and for a short distance along the main roads underground have been in operation for some time, and prove to be an effective and economical means of lighting where existing boiler and engine power can be utilised. No attempt has yet been made in this district to supply the miners with a portable electric lamp in place of the ordinary oil lamp, but several such lamps have been submitted to scientific societies, and I believe some hundreds are already in use in South Wales. Some of these lamps approach very near to what is needed. The introduction of a strong and reliable portable electric lamp would be welcomed, and its introduction would be the means of mining operations being conducted with much greater safety. The disadvantage of electric lamps is that they do not warn as well as protect. The motto of the old Davy used to be '*Moneo et Munio*,' whereas the electric lamp gives no sign of the character of the atmosphere it may be placed in, except by means of rather elaborate addition which could hardly be used by ordinary miners, but, even granting this drawback, I believe that their general use would be a great blessing, because the light within the lamp (burning in a vacuum) can be so securely isolated and protected that there would be little or no danger of the surrounding glass being accidently fractured."

Stronger Electric Ship Lights.—The following valuable letter has been addressed by Mr. J. Kenward, Birmingham, to the editor of the *Times*, calling attention to the necessity for stronger signal lights on shipboard, and some adjustment so that the penetrative power of the coloured lights at a distance shall be equal to that of the white. The question is well worth the attention of our ship electrical engineers, as a considerable amount of business may result to those who are best able to give practical attention to the matter. The letter is dated August 24, as follows: "Your correspondent, Sir Bradford Leslie, has done well to call attention to the subject of ship signal lights. It may be affirmed with absolute truth that the chances of safety of ships at sea with regard to collisions in the night are to a large extent in proportion to the power of the signal lights they carry. Most of the lamentable collisions of the past ten years are eloquent on this point. Unfortunately, the question asked in the Admiralty Courts and discussed in the press is simply: "Were the lights burning brightly (as seen by the crew that displayed them on each vessel)?" Not, rather, "What sort of lights were burning, and what was their penetrating power in average weather?" The whole question, indeed, is one of intensity in the first place, and of equality of intensity in the second place. White, red, and green are well-chosen distinctions for governing the evolutions of a vessel under steam, and I do not think that any arrangement of white lights alone would succeed. But it is surely obvious that in a triangular signal thus composed the three members of it should be visible at the same moment in nearly all conditions, whenever the lesser elevation of the side lights permitted. In no vessel afloat is this at present the case. In the majority of our vessels the lights have three essential defects: (1) The lenses are not of the best

Digitized by Google

optical character; (2) the oil flames are not the brightest; (3) the red and green beams are emitted from flames of equal power, with no adjustment in regard to the white. The loss of light through the best red glass is from 55 to 65 per cent.; that through the green from 70 to 85 per cent. This is a constant with all ship lights; but when a feeble flame and an ill-formed lens are employed, of course, the bad effect is enhanced. I have long, therefore, advocated the use of lenses of true optical character, and with flames so differently proportioned in the port and starboard lights that full equality with the mast light be attained. The most convenient way of effecting this is to introduce an electric incandescent lamp of, say, 200 candles into the green light, and another of, say, 100 candles into the red light. Then the emerging beams from the three would be nearly equal, and nearly equally visible at the same time. If better lenses were used, the distance also would be much increased. The statutory range is now five miles for the white and two and a half miles for the coloured lights. Little more, certainly, is ever attained with the red, much less with the green, and what this means in the case of vessels approaching each other at a combined speed of 30 miles, as your correspondent justly says, may be well conceived. It is, in fact, impossible to shape a course in time to avoid disaster, if disaster be impending. But with a concurrent range of at least six or seven miles for all the lights in clear weather, and some degree of visibility in weather when the old lights are invisible, a valuable security is gained, and a passenger may with confidence sleep through the night while the good ship is being driven at full speed on her way. The time will, I believe, come when that line of steamers will be preferred which is known to carry the most powerful and equally powerful signal lights. One company, at least, of high distinction is now preparing to give the new plan a trial, and the result may well prove that it is by no default of science that the imperfections of ship lights, with all the calamities they entail, have been so long endured."

Cowpen.—The temerity displayed by the Local Board at Cowpen in advertising for electric light tenders has called down the wrath of the *Blyth Examiner*. Cowpen is a portion only of the town of Blyth, and the *Examiner*, in drawing up a tabulated statement of the towns already furnished with the light, compares the position of Cowpen with them. "There are only (omitting from consideration London, which in spots, here and there, shows a little electric lighting) *twenty* places in which the public authorities have taken up this question? And these are not all *lighted;* some of them have only opened negotiations with electric companies, or perhaps it would be more correct to say the companies have only opened negotiations with the towns. So that perhaps not more than ten or fifteen towns are even experimentally lighted as yet. Of the above twenty, at least nine are fashionable watering-places, and there can be no doubt there is a rivalry among those places to keep up their attractiveness, and for that purpose money is lavishly and recklessly spent. Those nine places are Bath, Blackpool, Brighton, Cheltenham, Eastbourne, Hastings, Ilfracombe, Leamington, and Weston-super-Mare. The other eleven places are either cities, or very important towns worthy to be ranked as cities, if only on account of their wealth, and to whom an expenditure by way of electrical experiments comes only as a mere flea-bite. These towns are Barnet, Bradford, Dewsbury, Dublin, Edinburgh, Exeter, Glasgow, Leeds, Southampton, Taunton, and Waterford; and now we have to add that the Local Board for the district of Cowpen is nibbling at the flashing bait. Six of the authorities who are intermeddling with the electric light themselves own the gas undertakings, and may at once be taken out of the category of corporations who are actively opposed to the gas companies now existing; so that this list of twenty is thus reduced to fourteen. Out of this fourteen eight are rival and competing watering-places, spending money lavishly in the effort to keep their attractions to the fore; thus leaving throughout Great Britain and Ireland only six public authorities who on apparently ordinary grounds are introducing electricity for public lighting as a rival to gas now supplied by private companies. These are Barnet, Dublin, Exeter, Southampton, Taunton, and Waterford. Two of these are in Ireland, leaving only four for the other parts of the kingdom, and these are in England. There are also in the entire list of twenty only three Local Boards that have had the temerity to pledge the funds of their ratepayers to such purely speculative whims; the rest are municipalities of immense wealth, who can afford to run small experiments in favourite localities in their cities or boroughs—just as Blyth puts two Bray lamps in an important thoroughfare like Bridge-street. It certainly seems somewhat ridiculous that an unimportant place like Cowpen—part only of the town of Blyth—should place itself alongside of Barnet, Exeter, Southampton, and Taunton, and actually presume to teach all grades of corporations their duty as to electric lighting. If any electric lighting company contemplating tendering for the lighting of Cowpen district will first make a study of the facts and figures we have adduced, they will know more about the prospects of ultimate success with their speculation than they are likely to do from twenty interviews with that wonderful individual the 'surveyor to the board.'" And Cowpen, it adds, is the only town that thinks of entirely doing without gas, and prophecies its complete awakening in a fool's paradise. All this is very well on the part of the *Examiner*, and certainly shows an extended power of review on its part. But why not go a little further afield. If lamenting the absence of progress in England of electrical enterprises, large or small, as being to due Chamberlain's Act, why not ask what is done in countries unhampered by such an Act, as is now for the first time the position in England? Look at America for instances, where every little town of 5,000 inhabitants has its electric lighting plant, more often without gas than with it. Or if America is too far away, then France will give instances enough, and those rapidly extending, of little country towns, such as Mousson, where a double line of wire strung on neat poles all round the town carries lights driven by a water-wheel from the small waterfall at the town. Switzerland, Austria, and Italy furnish instances in considerable number of small electric lighting plants perfectly successfully undertaken, driven by steam as well as by water. The good people of Blyth and Cowpen may rest assured that if they go to the proper quarters they can ascertain exactly what *can* be done, can be referred to sufficient instances of what *has* been done, and may, if the conditions thus plainly enough stated satisfy them and their requirements, themselves become one of the first instances of what *will* be done in the electric lighting of small towns in England.

THE MAGNETIC FIELD.—II.

We have now touched upon the principal characteristics of lines of force, or, as we shall in future call them, "magnetic stream-lines," and we recapitulate the properties of our mechanical model representing a magnetic field as follows:—

The space within which the field exists is filled with a fluid in motion. The direction of flow in any point is indicated by stream-lines, along which a free magnet-pole is urged in the same manner as a material body would be urged by friction or impact. The force exerted upon that body is directly proportional to the absolute velocity of flow. The particles composing the fluid have inertia, but only in the direction of flow, and are not subject to the influence of centrifugal force. The particles attract each other in the direction of the stream-lines, but neighbouring stream-lines repel each other. The velocity of flow along any particular stream-line represents the force with which a unit-pole placed on that line would be urged on. This force may vary from point to point on the same stream-line. All the stream-lines are closed curves, whether they pass wholly through air or other non-magnetic substance, or partly through non-magnetic and partly through magnetic, or wholly through magnetic substances. The last-named property, although it cannot be directly proved by experiment, owing to the impossibility of placing an exploring-pole into the field where that is entirely enclosed in metal, is indeed self-evident from the consideration of the fact that the velocity of a column of fluid which has inertia cannot undergo sudden changes. If any stream-line were not closed on itself, the velocity of the fluid at its two ends would be zero, whilst immediately within these points it would be a definite quantity. This is physically impossible, as there must be a continuous supply of fluid at one end, and a continuous discharge at the other. The stream of magnetic matter must, in fact, behave very much like a stream of water kept whirling round by paddles or other contrivances in a circular trough. The width of the trough may vary from point to point, but the total quantity of water passing through successive cross-sections of the trough must be the same. The analogy goes even further; just as the moving water in our circular trough represents a certain amount of mechanical work, so does the stream of magnetic fluid require the expenditure of mechanical work in order to be started, and is capable of yielding up this work upon being stopped again. In other words, every magnetic field has inertia. Reasoning from analogy with the circular trough filled with water, we can make an estimate of the amount of inertia represented by a magnetic field. To simplify matters, we will assume that the trough has the same area throughout its circumference; the velocity of the water will then be the same all round, and the total inertia contained in the whirling ring of water will be proportional to the total mass of water contained in the trough and to the square of its velocity. Similarly, we should expect to find that the total inertia of a uniform circular magnetic field is proportional to the total mass of the magnetic fluid in motion—that is, the volume of the field, or more precisely, the volume of the ring of iron within which the stream-lines are supposed to flow—and to the square of the velocity of flow—that is, the square of the induction per unit area. We shall later on investigate this important problem regarding the inertia of a magnetic field more in detail, and then we shall find that the relation here merely foreshadowed by analogy with hydrodynamics is indeed correct. For the present, however, we need not make an actual determination of the energy of a field; before doing that it is necessary to show in a general way how this energy can become apparent in the shape of electrical energy, and to do this we shall endeavour to represent the interaction between a current and a magnetic field by means of a mechanical model.

Let the surface of the paper be pierced at right angles by a straight wire A, (Fig. 1), and sprinkle iron filings around the wire These will arrange themselves in the manner indicated in the sketch. Near the wire the filings lie more densely and further away from it they appear to be more thinly arranged. The stream-lines are in this case all circles concentric with the wire—that is to say, the magnetic fluid forms a whirl round the wire just as in a circular tank a whirl of water may be produced by revolving in it a central shaft provided with paddles, or by pushing a screw surface, say the propeller of a ship, vertically through the water. As the propeller descends in the middle of a tank, whilst itself prevented from rotating, its blades will produce a rotating motion or whirl in the water. If the diameter of the propeller is considerably smaller than that of the tank, the circumferential velocity of the water will be less at the outer periphery of the tank than nearer the centre, where the water is under the immediate influence of the propeller blades, and this will in a crude way represent the diminution in the velocity of the magnetic stream lines as we go farther away from the wire. We say in a crude way, because the change of speed in the mechanical model is necessarily somewhat abrupt, whereas in the actual field it is perfectly gradual. It has already been mentioned that a magnetic pole has a tendency to move along the stream-lines just as a solid body is urged along in the direction of the current when immersed in a fluid in motion. It might now be asked, "How is it that the iron filings sprinkled on the paper do not rotate around the wire?" Experiment does not reveal any tendency to such motion. All we observe is a tendency in the filings to crowd up to the wire; but beyond this movement, which is at right angles to the longitudinal axis of each particle, there is no movement in the direction of this axis itself. This absence of movement can only be explained on the assumption that whilst one end of the little piece of iron is impelled in one direction, the other end is impelled in the opposite direction,

FIG. 1.

that, in fact, there are two opposite and equal forces at work which can turn the piece of iron on an axis like a compass needle, but cannot move it bodily. We are thus compelled to assume the existence of two magnetic currents flowing within the same space but in opposite directions, one current acting upon the north and the other upon the south pole. We use the term north pole to indicate that pole of a compass needle which points to the geographical North. When speaking of the direction of lines of force it is customary to confine the term to those lines along which a free north pole tends to travel, corresponding in our new conception to the positive current of magnetic matter. A south pole would then be similarly affected by the opposite or negative current of magnetic matter. It is, however, not necessary to deal with both currents. We may disregard the negative current entirely, provided we bear in mind that the effect produced at the south pole of a magnet is always equal and opposite to that produced at its north pole. By confining our investigation to the positive current of magnetic matter (in the same way as we only speak of one current of electricity, although we should in reality speak of a positive and negative current which flow in opposite directions) we shall simplify the treatment without sacrificing scientific accuracy.

Returning now to our mechanical model of the field produced by an electric current flowing along a straight wire. We have represented this by the whirl of water in a circular tank set up by advancing a screw propeller along the vertical axis of the tank. The same effect might also be produced by a paddle-wheel, the boss of which is supported in collar bearings, and has a screw thread cut on the inside. Let the shaft of this paddle-wheel be a screw to fit the boss, and let the whole apparatus move frictionless. Upon thrusting the screw through the boss the wheel will

Digitized by Google

be set into rotation, and will impart rotary motion to the water. In this model the screw shaft represents the wire, the force we apply in thrusting the screw through its nut represents the E.M.F. applied, and the speed of advance represents the current, the moving water takes the place of the magnetic field, and the paddle-wheel is the connecting link between cause and effect. What the real nature of this connecting link is we shall not stop to inquire. It is at present beyond human ken, and will in all probability remain as much a mystery as the secret of gravitation and other natural phenomena, which are vaguely classified under the title "action at a distance." If we knew the mechanism by which these actions are produced there would be no need of casting about for mechanical models to represent such phenomena as we are now investigating. But as such knowledge is denied us, we must be content with more or less crude representations.

It will be convenient to arrange our model of the field surrounding a rectilinear current in a slightly different form. Instead of placing the water in an open tank, we suppose it contained in a cylindrical box, B (Fig. 2), and place the box with its axis horizontal so as to eliminate the weight of the shaft. Let a keyway be cut in the shaft to prevent it from turning by means of a feather, F, fixed in space, and let it be thrust through the boss of the wheel by means of a pull applied by a weighted cord going over a pulley, P. Let there be some friction in the pulley, which increases directly with the speed of its rotation. Now, if we place a certain weight, W, upon the pan, the shaft will slowly begin to advance to the right and gradually gather speed as the inertia of the water is being overcome by the paddles, A; but the increase of speed will not go on indefinitely; it

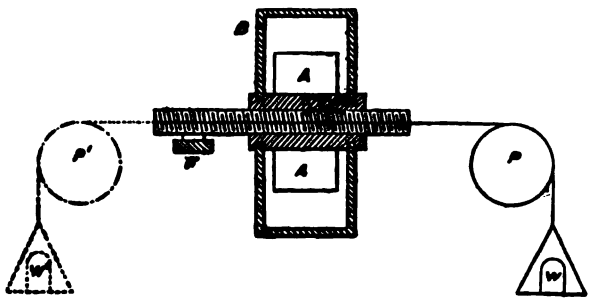

FIG. 2.

will only go on until the friction of the pulley has become equal to the weight. After this point has been reached, the speed of advance of the shaft remains constant. It is useful to observe that the final—that is, the maximum—speed attainable with any given arrangement is independent of the quantity of water contained in the box, and depends only on the weight in the pan and the coefficient of friction with reference to the speed. The mechanical process here explained at some length is an exact counterpart of the phenomena observable when a current is sent through a wire. Instead of the weight we have the E.M.F. of the battery or dynamo; instead of the friction of the pulley we have the resistance of the circuit, and the speed of advance of the shaft represents the current. The weight in descending has given out energy; a certain portion of this energy has been used up in overcoming the friction of the pulley, and is therefore lost. The remainder of the energy has been used up in imparting motion to the water, and as we have assumed that our hydraulic apparatus works without frictional or other losses, the whole of this energy must be considered as simply stored in moving water and as recoverable. Suppose, then, that after we have allowed the weight to act a sufficient time to produce the maximum or final velocity, we suddenly remove the weight. What will happen? Clearly the water will continue to revolve, and the shaft will continue to advance with the same speed as before the removal of the weight. If the advance of the shaft is not retarded by some opposing force, the energy stored in the system remains unaltered. Now suppose we take the cord off the right-hand end of the shaft and attach it to the left-hand end, taking it over the pulley, P′, which we assume to have the same coefficient of friction as the other pulley. The pulley, P′, will now be set into rotation by the cord, and its frictional resistance will cause a certain tension in the horizontal part of the cord, producing a pull to the left on the shaft. This will tend to retard the motion of the shaft to the right, and, consequently, also the rotary motion of the paddle-wheel. The water will now overtake the paddles and exert a pressure on their surface, which by means of the screw will be transformed into a push on the shaft directed to the right. In this way the energy in the water will gradually become exhausted, and motion will cease. The whole of the energy has in this case been absorbed by the friction of the pulley—in other words, has been transformed into heat. Suppose now that we had put a weight, W, upon the pan on the left. This weight would have been raised to a certain height before the water in the box could be brought to rest, and the energy contained in the water would in this case have been used up partly in the production of heat as before, and partly in raising the weight. Now, let us suppose that we put an excessive weight on the left pan, or that we suddenly clamp the spindle of the pulley, P, tight in its bearings, so as to prevent it from turning. This is equivalent to increasing the coefficient of friction to infinity. What will happen? The cord will stretch and finally break, and we can imagine the nature of its material to be such that the whole energy contained in the water becomes used up in producing the rupture.

(*To be continued.*)

LEAVES FROM THE DIARY OF A YOUNG ELECTRICIAN.

BY BROAD BENT.

(*Continued from page 162.*)

April 29.—A new engine-driver starts to-night. I had to get rid of the last because he knew too much—that is, he would not be told anything. The new man brings very good testimonials from previous employers, so perhaps he will be better.

One of the commutators is sparking fearfully to-night, and the brushes are so hot that they cannot be touched with the bare hand. The sparking is not the fault of the brushes, for I have just filed them all up and they are pressing very firmly on the commutator. We have only three more hours to run, so I will have a look at the commutator when we stop.

April 30.—Last night, when we stopped, I found that two of the segments of the commutator had worn quite flat, and a few of the adjacent ones were very much "pitted" with the flashing. The ends of the brushes, too, showed signs of the high temperature to which they had risen, many of the wires being fused at the ends into little balls of copper. The cause of the flat place was probably owing to the two copper bars not being so hard as the others, which would cause them to wear more rapidly. Having worn down a little, the brushes would jump each time the flat place passed them and spark. The heat of the spark would probably soften the surface of the bars still more, and so augment the evil. With a very smooth file I reduced four of the adjacent segments a little—that is, two on each side—then filed and emery-papered the whole until the surface was tolerably smooth. I then "set" the brushes, screwing them very firmly down on the commutator, but allowing at the same time sufficient spring to prevent them jumping over the "flat."

May 2.— The commutators are running sparklessly now; it would be impossible to tell that any current was passing. Several times to-night the lights have flickered; not an ordinary slight flicker, but they have gone down almost black. I can't make it out. It is said that incandescent lamps have a longer life with alternating currents than with direct, so I intend to reverse the dynamos every week, commencing to-night.

May 3.—I tried to reverse the dynamos last night, but did not succeed. I tried first by changing the terminals of the shunt wire, and "thereby hangs a tale," as Grumio would say. On disconnecting the shunt wire I found it was broken inside the insulation, a few inches from the

Digitized by Google

end. This undoubtedly was the cause of the lights flickering occasionally, but how the wire became broken "deponent sayeth not." When the two ends were in contact the current would pass, and the field-magnets be excited. Any extra vibration, perhaps that caused by a passing train, would separate them for an instant, thus interrupting the current, and allowing the field-magnet cores to become almost demagnetised, short-circuiting the other dynamo through the armature. Before complete demagnetisation could occur the spark of self-induction would probably fuse the two ends of the broken wire together, and the lights would go up again. All this would happen in a few seconds.

However, to solder these ends and cover up the joint was a matter of only a few minutes, and the reversing process was once more attempted. Having reversed the connections of the magnets, I told the driver to turn on the steam and run the engine for a short time. "Faster, faster," I shouted, "put on full speed." "It's faster now, sir, than we generally run," the man replied. Well, that's a strange thing, I thought, running full speed, brushes down, magnets connected up, and yet no current. "Stop her; we'll try some other way." I then altered the magnet connections to their first position and reversed those of the armature, but with the same result, "nary a light." "What a fool I must be!" I suddenly exclaimed, after considering a little while. "How on earth could those dynamos excite themselves?" I was glad no one was there to see what an ass I had been making of myself (of course the driver did not know what I was up to). I ought to have driven one dynamo as usual, and excited the other from it, but it was too late then, so I did what I might have done in the first place—*reversed the leads.*

May 4.—The engine-driver gave me a little of his history last night. From his own story he has had some rough times. His last job was out on the West Coast of Africa, where he had attacks of sunstroke and malaria fever, so he had to be sent home to the hospital. He may be all right, but men who have had sunstroke sometimes have slight attacks of madness. I hope he won't start any mad freaks here.

May 5.—I had an awfully lively time last night. The new engine-driver, after talking in a rather vague manner, went out to get "a half o' old six." It took him about three hours to get it. I thought he was never coming back. When he at length did return, I heartily wished I had never seen him, for the combined effects of the sunstroke, fever, and half-pint had made him *mad.* At first he wanted to fight. Well, I didn't; so he said he would put me in the fire-box if I did not stand up and put up my "maulers." I thought "discretion was the better part of valour," so tried to laugh it off, as though I thought he was joking. This succeeded for a time; but presently he began again. "I'm tired of life," he remarked; "aren't you?" "Well, not exactly," I replied; "but what's on?" "You'll see in a minute, boss," he remarked; "I'm just going to 'bust' this 'ere boiler!" So saying, he flung open the furnace doors, and then threw on shovelful after shovelful, till the fire-boxes were full up to the doors. He then pulled up the damper, and soon the fires were roaring. In a short time the steam was "blowing off" at the safety-valve, so this mad idiot went and sat on it. I immediately tried to close the damper, but my friend the madman threatened to fling a spanner at my head if I went near it. As might be expected, I was in an awful funk; was I to stop here and get blown up, or quit my post of duty and save myself? I was not long deciding, for the heat and the effects of the "half-pint"—which was probably not much short of half-a-gallon—made this unpleasant companion sleepy. So he left his position on the valve, and soon fell asleep on a bag of waste. I got on all right without him till "shutting-down" time, when he was still asleep. This morning he remembered nothing at all about the occurrence, but I must find some excuse for giving him the sack, as this sort of thing is unpleasant, to say the least of it.

May 8.—There is a signal-box just outside the "shed," which is in telegraphic communication with all the stations. When anything is wanted on any of the stations, the signal man sends "E L" (electric light) on the through instrument. They don't have occasion to send often, as we travel round frequently. The usual message is "Send the electric light man here at once." "The electric light man" (which means the machine man in charge at the time) then leaves whatever he is doing and rushes off with a pair of pliers, a screw-driver, a pocket knife, a few feet of wire, and one or two lamps, to find generally that there is one lamp out, owing to bad contact on the loops, which the least touch puts right again. If he happens to have been called away from dinner to attend so small a matter, he soliloquises on sanguinary matters, fools, thunder and lightning, &c.

The signal-box boy has just come in to say I am wanted at S.M. *at once; 5 lights out.* Now, I wonder what tools I want. Better take all the lot, to make sure.

(To be continued.)

ELECTROLYSIS OF SEWAGE.

The introduction of the use of the dynamo in any direction is interesting to all makers, but if it should prove useful in sewage purification a very large trade would be opened up. Mr. William Webster is the apostle of electrolytic treatment of sewage, and in the following notes of a paper, read before the Sanitary Engineers, he gives detailed information about his experiments. He says:

"It is quite ten years since I carried out my first experiments in electrolysis, but in those days the available electric apparatus had not attained such completeness as we now have it. I first of all wish to remove an impression which, I have been given to understand, is lurking in some minds—that it is impossible to electrically decompose pure water. Water is easily decomposed provided the current of electricity is of such intensity that it can overcome the resistance. Nicholson Carlisle decomposed water in the year 1800; the decomposing effects produced are precisely in accordance with the chemical equivalents of the substances electrolysed; for instance — the same amount of electricity that would reduce 56 parts of iron from its solution would reduce 207 parts of lead, or 16 parts of oxygen, &c. This is practically the explanation of the whole system; for the chemical changes which take place in sewage when it is electrolysed, depend chiefly on the well-known facts that water and sodium, magnesium and other chlorides (which are always present in sewage) are split up into their constituent parts. Thus, we have at the positive pole chlorine and oxygen set free, and these elements are liberated in a nascent state, a condition in which they are intensely active, so that the organic matter in the sewage is rapidly oxydised and burnt up to inocuous compounds. So rapid is this action, that I will now act on a little Crossness sewage, and produce a disinfecting liquid, which is nothing more or less than hypo-chlorous acid—the strongest oxydising agent that is known. To obtain this quickly, I must separate the positive action from the negative by a porous diaphragm. At the negative pole I obtain ammonia, potass, soda, magnesia, &c. So strong is the action of oxide of chlorine, that I have found no pressed carbon plates would stand its action; I am therefore compelled to use cut carbon or coke.

"It was this fact that made me investigate the cost, and the result was, knowing that iron salts were of great use in precipitating organic matter in solution, that I experimented with iron electrodes, for the oxydising acids produced by this action being probably 100 times more active than any acids produced by chemical processes alone, it necessarily followed that the iron salt produced must have similar properties. The nascent chlorine and oxygen generated partly unite, and, with the water, form hypo-chlorous acid; the positive iron plate being attacked and ferrous hypo-chlorite formed; but a portion of the hypo-chlorous acid attacks the organic matter, for it is well known that putrifying sewage has a strong affinity for oxygen.

"To still further strengthen this action, I have lumps of carbon cast into the iron plates, thus securing a supply of the before-mentioned acid.

"The iron plates are common casts run direct from the furnace into this form instead of pigs, and are used for the

positive poles, the negative plates being thin rolled sheet. The positive plates are gradually acted on by the acids produced, but the negative plates are not acted on, and will remain in the same condition for years. This is so well known that I need not enlarge upon it. I have estimated that the waste of iron at the positive pole is about one grain per gallon, but of course this entirely depends upon the electric current used. The hypo-chlorite of iron formed at the positive pole is acted on by the free ammonia, sodium, potassium, and magnesium hydrates and the ferrous hydrated oxide precipitated. This particular oxide of iron has the property of combining with organic matter, and it is a peculiarity of this salt to take a white hue, and then by exposure to the atmosphere to become green, and ultimately an ochrey red colour.

"This action can be seen almost daily in any dye-house during the dyeing of buffs. The cotton goods (representing organic matter) are dipped into an iron solution, and then passed through an alkaline bath. The shade is green, but slight exposure to the air produces the buff colour, the oxide of iron being precipitated within the fibres of the cotton. The ferrous hydrated or protoxide of iron is so beautifully precipitated, one may say, in its most active condition by this electrolytic process, that it takes up more organic matter than if precipitated chemically; for by chemical precipitation the iron oxide carries a large part of the suspended matter in the sewage with it, but only traces of the dissolved organic matter. In the electrical process, the whole of the matter suspended is carried with the oxide of iron, together with a considerable portion of the organic matter in solution, and, if necessary, the whole of the soluble organic matter can be oxydised. The precipitate itself is carried to the surface by the numerous bubbles of hydrogen issuing from the negative pole, and the effluent may be run off quite clear from below, or may be run with the precipitate into settling tanks, where the deposit will take place in from half an hour to two hours; the precipitate being exceedingly flocculent, subsides readily. The sludge formed does not hold so much water as by chemical process, and presses without any addition of lime. The effluent is less alkaline than the natural sewage, and, if necessary, can be rendered neutral by passing through coke filters arranged in such a way that the electric current can be applied, thus further purifying the effluent and delivering it in such a state that, personally, I should have no objection in drinking it. The reason of the alkalinity being reduced is that a small quantity of free ammonia is carried off with the hydrogen gas at the negative pole, and also by the formation of hypo-chlorous acid. It is by means of this coke filter that potable water can be purified either on a large or small scale, and the treated sewage is not liable to secondary fermentation, nor does it form a precipitate when mixed with ordinary river water. The chlorides are slightly diminished in quantity owing to the escape of nacsent chlorine at the positive pole. The amount of soluble mineral matter is not increased in quantity as in ordinary precipitating processes.

"The chloride of lime of commerce is really hypo-chlorite of lime. It has been suggested that the hypo-chlorous acid may possibly be as objectionable in its after effects as the salts of lime, but this is not the case, as hypo-chlorous acid is an unstable compound, which, having delivered up its oxygen in oxidising organic matter, changes into hydrochloric acid, which neutralises the alkalinity of the sewage.

"As I have already demonstrated that hypo-chlorous acid can be obtained in quantities by means of a porous cell enclosing positive pole, so likewise, by enclosing the negative pole, a solution of ammonia, &c., can be obtained from the raw sewage.

"I have brought with me a weak solution of the disinfecting fluid obtained from sewage twelve months ago; also a sample of an effluent eight months old. I have shown that the sewage can be purified to any extent, even to conversion into a disinfectant. It therefore only remains for me to enter into the question of cost, which I will do as briefly as possible, and it is just as well to mention that this will be partly ruled by the particular state of purity you require your effluent.

The chief expense is the engine-power. My experience up to the present time is limited to treatment of about 100 gallons of sewage at any one time; and from a large number of experiments, I found it would be possible to treat this quantity with about ½ h.p. The dynamo and engine were unsuitable for my experiments, as the dynamo was only fit for electric lighting, and the engine 25 years old—without a governor. I should, therefore, prefer to think the h.p. over-estimated. The time occupied in treating every 100 gallons varied from five to ten minutes. The consumption of iron was one grain per gallon. The cost of this is easily estimated when one knows the market price of pig iron. By kind permission of the Metropolitan Board of Works, I have erected works at my own expense at the Crossness Outfall of sufficient capacity to treat sewage at the rate of one million gallons per diem. As I have sufficient confidence in this process to risk the large outlay entailed. For this I have had an Edison-Hopkinson dynamo specially constructed, giving an output of 1,600 amperes and 20 volts.

"Unfortunately the electrical portion of the works is not yet completed, or I should have hoped to have had the pleasure of inviting you to inspect them.

"The question of cost resolves itself into this: The more iron plates you introduce into the system, the greater the surface, and the lower the resistance, consequently the less H.P. required. The increase of the iron plates is only an increase of prime cost, and does not mean a greater waste of iron; this means a saving of labour as the more iron originally used the less frequently would require renewal.

"I hope to prove that by using positive plates 1in. thick their duration will be from five to ten years. If the proportion of ½ h.p. to 100 gallons in 10 minutes holds good, as I am inclined to think it will, then 25 actual h.p. would be capable of purifying 1,080,000 gallons of sewage in 24 hours. I should much have liked to have gone into more minute details connected with these experimental tests, but until I have verified the present results on a practical working scale, I feel it would be premature to quote figures."

The results of a few analyses of sewage before and after treatment are given in Table A. (*See* above.)

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, ESQ., *President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of* W. H. WOLLASTON, M.D., F.R.S., *and on April 20th we gave that of* SIR HUMPHRY DAVY, F.R.S., *whose fame as an electrician is still more prominent than that of* WOLLASTON. *Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of* PROF. D. E. HUGHES, F.R.S.

ESTIMATING.

There is a complaint heard from all quarters that profits are too low, because of the tendency of weak firms to lower prices to starvation point in order to obtain a semblance of work. It is well known that tenders have been sent in for various works during this year of grace at so low a price that other tenderers have wondered how it was done. The same system has been pursued in other industries, with the result that sooner or later the weak firms went to the wall and prices stiffened. Sometimes "rings" have been formed to regulate prices, and in certain cases with a considerable amount of success. It is not so very many years ago that the steel industry was dominated by such a ring. For a time again tube makers acted together in harmony. We should hardly care to suggest any such attempt to regulate prices with regard to electrical apparatus, because any such suggestion would savour of the ridiculous rather than the practical. The same conditions do not hold in this trade as held with regard to steel rails, or with tubes, but we can do no harm in suggesting caution to reckless traders. In not a few instances that have come under notice the errors have evidently arisen through ignorance, and it is with a view of pointing out this weakness very clearly to those who have in some way the power to overcome it that we venture to make these remarks. A short time ago we recorded a very pleasant evening when Messrs. Crompton met their old and present pupils at dinner at the Holborn Restaurant. Among the speeches made was one by Mr. Albright, who dwelt specially upon the fact that part of the training consisted in "learning to estimate." Now, with the exception of men trained in some such practical establishment as this, we venture to say that few of those who enter the profession ever had the subject of estimating presented to them in any shape or form. A large number of men have received their training at special schools, such as those at Princes-street or London Bridge, or at the City and Guilds Institute, or at the colleges at Bristol, Liverpool, Nottingham, Dundee, Aberdeen, Glasgow, &c., but has one single man from any of these educational establishments ever spent an hour in getting out a practical estimate in connection with a given specification? When he enters into business, as he frequently does with little or no other than the training thus received, he has to prepare estimates, and he may do so in two ways—correctly or incorrectly. If the estimate is prepared incorrectly it may be too low or it may be too high, and it may be politic to say in either case a loss is sustained. The work being estimated for at too low a figure, is obtained, and a direct loss results; estimated at too high a figure, profits that might have figured in the firm's books do not appear, for the work is given elsewhere, and so a loss is sustained, if that can be

Digitized by Google

called a loss that was never in one's possession. "Quantities" is a familiar word with builders and architects, and the former base their estimates upon the quantities taken out under any design of the latter; but quantities are as important to electrical contractors as to builders, and should be as carefully considered by the one as by the other. There are plenty of surveyors who make a speciality of taking out quantities for builders; but we doubt if, outside half-a-dozen well-known firms, electrical quantities are ever taken out with any degree of accuracy, and hence the estimates founded upon inaccurate quantities must be many. We recently heard of a firm—not an electrical one—where the partners could not understand why the bank balance was so bad. It was thought and maintained by one of the partners that a gross profit of 60 per cent. was being made, and as the business was very large the net profits should have been considerable. When a thorough investigation was made by the accountants the gross profits were found to be about 40 per cent., a difference of 20 per cent. through mistaken calculations, and it is easy to understand that the net profits had vanished. Here an expected balance to the good of about £5,000 became really a balance to the bad of about £500. So far as the ordinary small installations are concerned, there should not be much room for difference in prices, and yet the outsider would be astonished to see the great difference that really exists in tenders. The tendency of the man ignorant of the true method of estimating, is towards too low a price. He lumps items that should be calculated separately, and, by rule of thumb, dashes at items that are foreign to his experience. The working man, too, is expected to do an ideal day's work—one that may conscientiously be performed in the millenium, but not now; he reckons upon purchasing materials in units at the same price as they are quoted per gross, altogether believing he is approximately correct, and has allowed a 20 per cent. net profit. Happy is the man who starts in business knowing his weakness. A careful consideration of the whole matter will show that the plan explained by Mr. Albright is of the greatest value to those who subsequently become principals in business, or on the estimating staff in large establishments. Imitation being the sincerest form of flattery, we suggest that it is not impossible to imitate Messrs. Crompton, so far as this particular question is concerned, in some, at any rate, of the educational establishments to which we have alluded. Quite lately, critical remarks have been made about a certain specification, but, after all, a debt of gratitude is due to the author of that specification for writing it. Whatever may be the individual opinion as to its good or its bad points, there it is, a guide useful to a very large number of men who have never previously seen a specification of the kind. However, to return to the moral we have endeavoured to instil, the contention is that not only is it necessary to know how to do the work, but it is essential also to know how to charge for the work. Ignorance of the one is as vital as ignorance of the other.

CORRESPONDENCE.

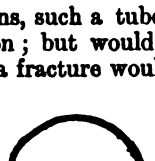
COPPER TUBES.

To the Editor of The Electrical Engineer.

Sir,—In reading the account you publish of the examination of that copper tube which burst on board the ss. "Elbe," it seemed to me that the effect of the expansion of the unaltered portion of the tube upon the part rendered more brittle by brazing would be to produce a further strain upon this latter portion, in addition to that which it was already receiving from the direct effect of the pressure and temperature of the contained steam.

For that part of the copper tube which was not deteriorated by brazing would attempt to expand naturally, while under the influence of steam pressure and heat, by virtue of its unaltered properties, while the portion which had lost these properties could not do so, and therefore would have to bear the strain due to the expansion of the adjacent metal pulling on it, in addition to such other strains as were common to the whole circumference of the tube, while the direction of this additional strain would be such as to produce or increase an internal longitudinal fracture along the line of greatest brittleness.

Under these conditions, such a tube would not be perfectly circular in section; but would have a depression at the brittle part, where a fracture would occur.



I think that such a fracture as was found would be produced upon the first occasion that full pressure steam was admitted to the pipe, and so would allow a certain amount of expansion in the neighbouring parts, and a consequent diminution of the strain due to it to take place; after which the ordinary steam pressure might be borne for some time, as the strains from inequality of expansion no longer exist.—Yours, &c., Harold G. Dixon.

Guy's Hospital, S.E., August 26th.

INSTITUTE OF MEDICAL ELECTRICITY.

To the Editor of The Electrical Engineer.

Sir,—In reply to the letter of "Alpha" in your last week's issue, I desire to point out that this institute is "established in the West-End of London," and is fitted (or, more correctly, is being fitted) with "the best apparatus" that can be obtained. Further, I would say that electromagnetism will have its full share of consideration here, and such use and recommendation as the results of experiment warrants, in common with other forms of electrical treatment which have, or claim to have, any use for curative purposes.

If "Alpha" will kindly let me know his name and address, I will gladly send him full particulars of the institute and its objects.

With regard to "Alpha's" last paragraph, and Mr. Herford's letter on the same subject, I will only say that I have received a communication direct from the latter gentleman, and that its subject-matter is under the consideration of the directors.

Perhaps you will allow me to add that, in fulfilment of the intention stated in my letter of the 17th inst., we have secured the services as physician to the institute of a medical man of excellent standing, who for some years past

Digitized by Google

has had special experience of electro-therapeutics in one of the large London hospitals, and has now entered very earnestly into the work of the institute.—Yours, &c.,

H. NEWMAN LAURENCE, Managing Director,
The Institute of Medical Electricity, Limited,
London, S.W., 29th Aug., 1888.

SPRAGUE MOTOR CURVES.

BY FRANK P. COX, B.S.

The method used in obtaining these curves is known as Hopkinson's method.

Excepting the dimensions of the machine, only one measurement is necessary. That is to determine the value of the constant ν. This value is the ratio of the total lines of force through the field-magnets to the useful lines through the armature. I have previously described the method of finding an expression for these lines. In this case $\nu = 1{\cdot}76$.

It is also necessary to have a curve representing the relation between the magnetising force H and the permeability, μ for wrought iron, and a similar curve for cast iron.

Hopkinson gives curves for cast and for wrought iron, showing the relation between B, the magnetisation and H. From those curves several values of μ have been worked out, and the following curves constructed:

Cast iron.		Wrought iron.
μ	H	μ
400	10	1,130
270	20	700
207	30	495
168	40	384
140	50	315
121	60	268
108	70	233
98	80	208
90	90	188
84	100	170
71	125	135
61	150	117
51	200	92

The method of using this curve will be described later. We must now make use of Hopkinson's formula to find the required magnetising forces.

The formula is

$$4\pi n c = l_1 f\left(\frac{I}{A_1}\right) + 2l\frac{I}{A} + l f\left(\frac{v\,I}{A}\right) + 2 l f\left(\frac{I}{A}\right)$$

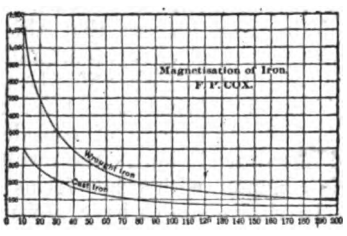
Where

"n" is the number of turns on the field,

"c" the current in C.G.S. units,

"I" represents the induction and is the quantity we wish to find the value of.

"l_1" is the length of the lines of force in the armature, and is slightly greater than the shortest distance between the pole-pieces. It is in this case 10 cm.



"A_1" is the cross-section of the iron in the armature, and is ·9 of the total cross-section in a horizontal plane; 10% being allowed for lamination. A_1 is 224 sq. cm.

"l" is the perpendicular distance between the faces of pole-pieces and the armature core. l_2 is ·7 cm.

"A_2." This is the area of the face of pole-piece, + 13%, to allow for dissipation of field. It is 286 sq. cm.

"l_3" is the length of lines of force in the field—that is, the length of the field core. It is 16·8 cm.

"A_3" is the area of the field cores, and, since there are two magnetic circuits in parallel, twice the area of one magnetic limb will have to be used. A_3 is 153·4 sq. cm.

"l_5" is the length of lines of force in pole-piece. This cannot be measured *exactly*, but is approximately 21 cm.

"A_5." As in the case of A_3, the mean area of cross-section will have to be doubled, giving 198 sq. cm.

"ν." As stated before, ν is 1·76.

The formula now becomes

$$4\pi n c = 10 f\left(\frac{I}{224}\right) + 1{\cdot}4\frac{I}{286} + 16{\cdot}8 f\left(\frac{1{\cdot}76\ I}{153{\cdot}4}\right) + 42 f\left(\frac{I}{198}\right).$$

It is now necessary to substitute for the functions their values, and to divide the equation up into its parts. The first term represents the force required for the armature, the second that for the air space, the third for the field, and the fourth for the pole-pieces. In the equations the functions may be expressed by multiplying the term by $\frac{1}{\mu}$. Now, to obtain the curve for the armature we vary the magnetising force $x = \frac{10\ I}{224\ \mu}$ and for the different assumed values of x work out the value of I. The curve is then plotted with these values of x and I. In a similar manner the curves for the other parts are constructed. The air space will in every case be in a straight line. Before discussing the characteristic curve it may be well to construct the other curves, as the characteristic is taken directly from them.

We have for the armature

$$x = \frac{10\ I}{224\ \mu} \text{ or } I = \frac{224}{10}\mu x$$

For the air space,

$$x = \frac{1{\cdot}4\ I}{286} \text{ or } I = \frac{286}{1{\cdot}4} x$$

For the field,

$$x = \frac{29{\cdot}6\ I}{153{\cdot}4\ \mu} \text{ or } I = \frac{153{\cdot}4}{29{\cdot}6}\mu x.$$

For the pole-pieces,

$$x = \frac{42\ I}{198\ \mu} \text{ or } I = \frac{198}{42}\mu x.$$

Now, when we give to x different values, the value of I for each one is easily worked out, since μ depends directly upon x, and its value can be obtained as follows: Since x represents the total magnetising force, we must divide by the length of the line of force to obtain the magnetising force per unit length. Now, having obtained this value, we look upon the magnetisation curve, which is plotted in terms of μ and magnetising forces per unit length. This curve gives us the value of μ for this value of x, and having this the value of I follows directly. The following tables give values required in the construction of the curves:

ARMATURE

$\frac{x}{l_1}$	x	μ	I
5	50	1,550	1,736,000
10	100	1,130	2,531,200
30	300	495	3,326,400
50	500	315	3,528,000
80	800	208	3,727,360
100	1,000	170	3,808,000

AIR SPACES

x	I.
1,000	204,300
2,000	408,600
3,000	312,900
4,000	817,200

FIELD.

$\frac{x}{l_3}$	x	μ	I
5·95	100	1,410	730,380
17·85	300	765	1,188,810
29·75	500	497	1,287,230
47· 6	800	328	1,359,232
59· 5	1,000	270	1,398,600

Digitized by Google

POLE-PIECES.

$\frac{x}{2l_5}$	x	μ	I
7·14	300	442	624,546
11·9	500	370	871,350
19·04	800	280	1,055,040
23·8	1,000	242	1,139,820
47·6	2,000	146	1,375,320
71·4	3,000	104	1,469,520

CONSTRUCTION OF CHARACTERISTIC.

From any point on the air space line lay off an abscissa equal to the sum of the abscissæ of points in the curves for armature, field, and pole-piece, whose ordinates are equal to the ordinate of the selected point in the air space line. This point will be a point in the characteristic curve. Any number of such points can be similarly obtained and the curve drawn through them. This construction does not take into account the effect of the current in the armature, as in this particular machine its effect is practically zero.

We have now all the data required to construct any size dynamo or motor of this type. Suppose, for instance, we wish to build a dynamo of this type with a given number of armature coils to give a certain potential at a given speed of rotation.

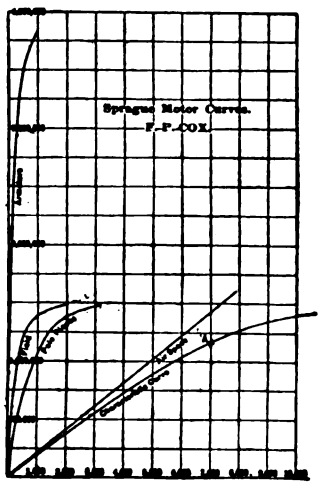
On the characteristic take A before the curve becomes too nearly horizontal. The induction for this point is 1,150,000, and the magnetising force 7,000 C.G.S. units. The potential this dynamo would develop at the given speed is given by the formula:

$$E = \frac{n r I}{100{,}000{,}000},$$

where

E = volts developed.
n = number of armature coils.
r = revolutions per second.
I = induction.

Now, this value is, perhaps, too small, and a larger machine will be required. Silvanus Thompson tells us that "if the linear dimensions of a dynamo be increased n times its output is increased n^3 times. This rule is only approximately true; so that when we select n so that $n^3 E$ = the required potential and construct a new set of curves, we shall find that they are not exactly right.



From this new characteristic we calculate the volts which would be developed at the stated speed, and find that it is either a little too great or small. Some small changes will have to be made in different parts, until, by successive approximation, the required potential is obtained. It is now necessary to know how strong to make the field. The magnetising force required to produce this induction is expressed by— $H = 4\pi n c$,

or $$n c = \frac{H}{4\pi};$$

but this is expressed in C.G.S. units, and will have to be multiplied by 10 to be expressed in units in daily use, giving the required ampere turns $= \frac{5H}{2\pi}$. A few words upon size of wire to use may not be out of place. We know the potential at the terminals, and can approximate to the external resistance, and, therefore, as to the current which will flow through the armature, and thus calculate the size wire required from the following rule: Wires to 2mm. diameter can safely carry five to six amperes per sq. mm., and wires of 5mm. diameter can safely carry three amperes per sq. mm. For the field, if it is a shunt machine, its resistance should be at least 364 times that of the armature, so that we can choose any resistance greater than this, only remembering that it must be the resistance of wire of proper size to carry the current, and of such length as to give the correct number of turns.

THE INFLUENCE OF HEAVY ELECTRIC CURRENTS ON TELEPHONE LINES.

The German Society of Electricians in November last appointed a committee to investigate the conditions under which telephone circuits can be efficiently operated in the neighbourhood of cables carrying heavy currents, such as are used for electric lighting and transmission of energy. The problem put before the committee was formulated as follows: (*a*) How are telephone currents influenced by heavy electric lighting and power currents in their neighbourhood? and (*b*) what conditions of installation and working heavy current circuits should be observed in order to avoid interference with neighbouring telephone circuits? The committee, as originally constituted, contained ten members, but they added four other members of the society to their number, and elected a sub-committee to prepare the experiments. The committee have now presented their report, which is printed in the society's *Journal* for August. The space at our disposal does not permit us to give a full translation of this report, and we must content ourselves with citing only a few of the experiments, and giving the general conclusions arrived at by the committee.

Experiment I.—The testing wire of an electric light cable 500 metres long, and carrying a continuous current, was used for telephonic communication, with the result that, in addition to the ordinary noises heard in the telephone, there was a disagreeable and persistent surging sound which greatly interfered with the clearness of transmitted speech.

Experiment III.—A telephone cable drawn through an iron pipe was placed underground at a distance of 1 to 1½ metres from, and for a length of 550 metres parallel with, several electric light cables carrying continuous currents. No noises, other than those usual, were heard in the telephone, and conversation over the telephone line was quite satisfactory.

Experiment IV.—In this experiment an overhead telephone circuit was used, passing over a railway station lighted by alternating currents. The telephone wire crossed the main cables at right angles, but was about 20 metres above the dynamo-room. Notwithstanding this disposition, there was produced in the telephone a humming noise which greatly interfered with the transmission of speech.

Experiment VIII.—An alternating current of 120 amperes was sent through a concentric cable, and an insulated telephone wire was laid underground by the side of it. No noises were heard in the telephone.

Experiment IX.—Instead of a concentric cable, two single cables were used, carrying a current of 58 amperes, and placed 15cm. apart, the telephone wire being laid midway between them. In the telephone there was noticed a low whistling sound, but not sufficiently strong to interfere with communication.

Experiment X.—The electric light circuit was arranged as in the previous experiment, but the telephone wire was placed outside of them, with the result of inducing a humming noise in the telephone which greatly impeded communication.

Further experiments were made to ascertain the effect of an iron armature on the cables, and a metallic return for the telephone circuit. It was found that telephonic communication remained undisturbed by neighbouring heavy

Digitized by Google

currents if the lead sheathing of the telephone cable was used as a return circuit. Where, however, earth was used, noises could be detected in the telephone, and it was also found that the influence of heavy currents upon neighbouring telephone circuits depended upon the earth resistance of the latter.

The general conclusion arrived at by the committee is that it is not possible to give the precise limit for the distance at which parallel telephone circuits and cables carrying heavy currents should be placed in order to avoid interference, but that this distance should be made as large as possible, not only to reduce induction, but also with regard to the greater mechanical safety of the telephone circuits. Where alternating currents are used interference can be avoided only if both the positive and negative mains are equi-distant from the telephone circuit, a condition which is fulfilled by the employment of the Siemens' concentric cable. The same arrangement is also advisable where continuous currents are used. Interference is avoided if the telephone circuit is operated with a metallic return placed close to the outgoing wire. The report concludes with a recommendation that telephone and electric light or power circuits should be placed as far apart as possible, and should be protected by a metallic armature. It will be seen from the above brief review of the labour of the committee that the results they have obtained are in accordance with the generally accepted views on the subject, and that the recommendations are of such a nature as would naturally be adopted by any competent electric light or telephone engineer, even had these long series of experiments not been undertaken.—*Industries.*

ELECTRIC TRACTION.

M. G. de Coetlogon has recently contributed an article in *Le Génie Civil* on this subject, in which he gives a compendious account of the different systems in use. The author commences by pointing out that electricity substitutes for horses one central station equipped somewhat as follows:

1. Some kind of general motor.
2. Generating dynamos, or the charge in the case of accumulators.
3. A motor upon the vehicle operated by the power conveyed or stored.

The author claims that electricity presents a marvellous elasticity, in enabling the management to supply more or less power and velocity as required without an appreciable addition to the expense. And the further claim is made that "existing experiments show that the expense of electrical traction is 40 per cent. less" than by the use of horses for the same purpose.

Then follows a description of the three principal systems in use for moving the vehicle itself; leaving out of consideration here locomotives operated by electricity, as requiring a dead weight out of proportion to the service, and as presenting a waste of space in the length of the moving power.

1. *By Cogwheels (Frankfort).*—In this system a pinion, keyed upon the axle of the motor, meshes with a wheel, with 56 teeth, revolving upon an intermediary axle. A second pinion moves a wheel with 52 teeth, fixed upon the main axle of the car. The proportion is 6·6 to 1 between the motor and the driving wheels of the vehicle. This motor has a movement of about 500 revolutions per minute. The inconvenience of this system is that it is noisy, and easily broken or damaged.

2. *By Chain and Sprocket Wheel.*—In this machine the motor makes 1,000 revolutions per minute, and carries upon its axle a small pulley, the circumference of which is cut in V-shaped grooves. This pulley, by a belt of steel wires, controls a large wheel with similar grooving, fixed upon the frame of the car. The movement of this intermediate wheel is then transferred to the driving wheel by the aid of a pinion and a sprocket-chain and wheel. This is the system more generally used.

3. *By Steel Wire and Grooved Pulleys (Lichterfeld).*—Here the axle of the motor, fixed in the centre of the car, carries a pulley, in which the width is about 6in., and it is cut into twenty-four V-shaped grooves. Each of the two main axles of the car carries a large belt-wheel on its centre, with the rim of the belt-wheel cut with twelve grooves. The pulley is placed 2·95ft. from the centre of each of the two larger ones. In the grooves of the pulley run twenty-four cords of a special steel wire, which alternate so that twelve of these cords pass over each of the main pulleys. These steel cords are formed of two wires, each two millimetres in diameter, wound upon a core three millimetres in diameter, in such a manner as to make a rigid though flexible spiral cord of 5½ millimetres in diameter. This system is very simple and strong, and the carriage upon which it was first placed has already made an aggregate run of more than 248,000 miles without any breakage.

Motive Force.

There are three means of supplying electric energy to the car—viz.: (1) By primary batteries carried in the car. (2) By conveying the power to a distance. (3) By accumulators.

1. *Primary Batteries.*—Under existing circumstances this method must be rejected, as it is not commercially practicable on account of the weight, space occupied, and the delicate manipulation and other disadvantages.

2. *Transport of Energy.*—To this system belongs a central generating station provided with its general dynamos, and from which the electric force is conveyed to the car either by the rails themselves or by a special aerial or terrestrial conductor. If the transmission is by the rails, the axles are insulated from the wheels, and the motor receives the current from the dynamo generally by metallic brushes striking upon wheels which roll upon the conducting rail.

When the transmission is by aerial or underground conductors, the latter being enclosed in a buried tube with an upper slot, a small chariot hugs the conductor in the tube, or runs on wires supported on poles; and by a flexible cable conveys the electric current to the car-motor.

This transport system, more generally applied at present than the accumulator system, works very well, but there is much waste of energy in the transport. The resistance of the conductors being generally great, it is necessary to employ currents of high tension, which during their passage may cause accidents.

MM. Pollock and Binswanger have devised a special and ingenious arrangement, which seems to reduce the dangers above referred to. This is an insulated cable conductor, brought into action by a powerful magnet suspended under the car, with a third sectional and articulated rail. On the passage of the car, the attraction between the third rail and the magnet establishes between the cable and the rail a temporary contact, which ceases altogether when the vehicle has passed by.

Another inconvenience of the transport of electric energy by conductors is the waste of power, which increases with the distance from the central station. The longest line now operated on this system is that of Portrush, in Ireland, about 5·9 miles in length.

3. *Accumulators.*—This is the most seductive of all the systems proposed. By it the vehicle is rendered independent; it carries its own force within it to any desired distance according to the power stored. It is not tied to the bank, so to speak, by a wire or rail, for it may even leave the rail proper, and still be self-moving. If the places in this car are not all taken, the reduction in weight is a gain, for the car charged to run only 50 miles may possibly be transported twice that distance with the same reservoir of electric force. This mode of traction permits of a decrease in the length of the run by an increase in the normal velocity, and can command at will the extra power required for mounting grades.

Unhappily, the gain in power means an increase in dead load, due to the accumulators, and there is a commercial limit in this direction. It is true that this disadvantage is not peculiar to electric traction, for any other system of mechanical traction, by steam or compressed air, is subject to the same fault.

In present experiments in this direction the batteries are disposed under the seats in the car, or under the floor. To assure a force sufficient for a daily run of forty-eight to

Digitized by Google

sixty miles for each car, it is necessary to arrange the batteries so that they can be readily replaced by new ones when emptied of their charge. And owing to their weight and the limited space in which to carry them, an electric capacity equivalent to 28 to 30 miles' run is the practical limit. The battery of accumulators generally weighs about one-third of the total of the car, the passengers, and motor mechanism united in the case of a 30-mile run equipment. To supply 60 miles per day, the battery will equal in weight the whole useful load.

The only fault of this traction system is thus in the excessive weight required in the dead or non-paying load, or the weight of the lead accumulators which Messrs. Julien and Reckenzaun employ. While they have attempted to reduce this load, the results do not yet give complete or sufficient satisfaction. The "horse-hour" stored weighs more than 110lb. When this can be reduced to 40, or better to 20lb., the accumulator system will be commercially practicable. In present practice the accumulators are charged at the station by the use of a dynamo and then put in place upon the tramway; one battery is recharging while the other is in service.

Existing Electric Traction Enterprises.

1. *Elevated Railway (in New York)—Transmission by Rail.* The experiments during the last two years on the Third Avenue Railway were on a line about 20,000ft. long. Traction was secured by a locomotive of the Steven and Field system, weighing 26,000lb.; of this 18,000lb. was in the motor. This engine draws three cars and 300 persons with a mean velocity of 7·8 miles per hour. The electric current from the generating dynamo was 40 amperes, with E = 800 volts—say, an electric energy of 32,000 watts-hour.

Electric Railway in Minneapolis, U.S. Transmission by Rail.—This line is a little over one mile long. It was intended to replace a section of ordinary railway over which the authorities had forbidden the use of steam. Each train is made up of three or four cars, transporting 600 people, of a total weight of about 90 tons. The speed is 16¾ miles per hour with a motor of 40 h.p.

Other American Lines.—Besides these two lines there are more than fifty towns in the United States having electric railways of some kind. All are in regular use—have been for some time—and give satisfactory results. The mean expense per car-mile is 3½d. to 4d.

Blackpool Railway (England). Transmission by Conduit.—This line is about 2 miles long. The rolling-stock consists of various types of carriages containing 30 to 56 passengers. The initial E.M.F. is 220 volts, which are reduced to 158 at the extremity of the line. The motor-engine is of 50 h.p., and the expense per car-mile is about 4d.

Portrush Railway (Ireland). Transmission by a Third Central Rail.—This line is 5·9 miles long. The generator at the central station is an hydraulic force of 100 h.p. The dynamo-generator gives a current of 100 amperes, with a tension of 250 volts. The motor-car will carry fifty passengers, and haul three cars of freight.

Bessbrook Line (Ireland). Transmission by a Third Central Rail.—Here the main generating force is also hydraulic, supplying 62 h.p. to two dynamos, credited with 100 amperes and 250 volts. This railway does regular duty in the transport of passengers and merchandise. The average speed is 8·7 to 9·3 miles per hour upon an undulating route of three miles in length. The motor-car will carry 40 passengers, and each of three waggons making up the goods train will carry 2 tons. In 1887, with 1,000 trains, the line transported 150,000 passengers and 1,500 tons of merchandise. The total expense of traction, including salaries, repairs, sinking fund, and motive-force, is about 4d. per train mile.

Brighton Tramway (England). Transmission by Rail.—This road has been in service since August 2, 1884, and runs from Brighton to Kemptown. The line has very steep grades, and a total length of about one mile. The motor-car carries 30 passengers, and weighs 10,450lb. The average speed is eight miles per hour. The service is very active in summer, and almost nothing in winter. Last year it transported 200,000 passengers. The expense per train mile does not exceed 3½d. The central station has a gas-engine of 12 h.p. driving a dynamo generator giving a current of 20 amperes with an E.M.F. of 160 volts.

Moedling Line (near Vienna). Aerial Conductor.—This line is 2·8 miles long. The line is one succession of grades, and the difference in elevation between the extremities is 1,180·8ft. All the expense of motive power is in the ascent, as the train returns by gravity, controlled by powerful brakes. As at Brighton, the important traffic is in summer. From April to November, 1887, it transported 350,000 passengers. The car weighs 8,800lb. net, and carries 25 people; a total weight of about 12,760lb. The ascent is made in 16 minutes, or at the rate of about 10 miles per hour. The electrical station includes three engines of 12 h.p. and six dynamos, each giving a current of 30 amperes with an E.M.F. of 500 volts. The potential difference is 500 volts at the Moedling station to 290 volts at the summit of the line. The average expense is 3½d. per mile run.

Frankfort Railway to Offenbach. Aerial Conductor.—The road has a regular service of 4·1 miles, with steep grades. Trips are made every twenty minutes; and the run is made in forty minutes, thirty-two for traction, and eight minutes consumed in eight stops. The line has been working since 4th April, 1884. The expense is about 4d. per mile run. Each carriage, with its dead load and passengers, weighs 18,370lb., and carries 48 people. In 1887 it transported more than 1,000,000 passengers. The central station utilises two engines of 60 h.p. and four dynamos, giving each a current of 70 amperes with an E.M.F. of 300 volts.

Lichterfelde Railway (Berlin). Transmission by Rails.—This is the oldest of all electric railways, having been opened on May 12, 1881, between Lichterfelde and the military school. The line is 1·5 miles long, and the carriage carries 24 passengers, and weighs, in all, 10,560lb. It makes the run in eight minutes at an average speed of 11 miles per hour. Each car makes 24 trips per day regularly; or a total daily run of 36 miles. It carried over 100,000 passengers last year. The plant includes two steam-engines of 6 h.p. and two Siemens' dynamos.

The author confines himself to the description of the above lines, as other existing lines are only copies of these.

Traction by Accumulators.

Rochdale Railway (England).—This line is about 3·1 miles long, with steep grades (111·5ft. difference of elevation). The carriage is very light, weighing only 4,400lb., and comprises in itself transmission motor and brakes. The battery is made up of 80 accumulators, weighing 39·61lb. each, or about 3,300lb. for total weight of battery. The carriage capacity is 20 passengers of 156lb. each, so that the total weight to be hauled is about five tons.

The electric motor has a nominal power of 10 horses and weighs 594lb. This machine makes 1,000 revolutions per second, with a maximum current of 40 amperes and 160 volts. This velocity is reduced in the ratio of ten to one by a transmission made by an intermediate axle and sprocket-wheels and chains. A compensator is arranged to bring reserve power into action; so that in case of breaking away on a steep grade a force of 12 or 15 h.p. can be commanded.

Electric Tramways of Brussels.—There are two lines here that have been in regular service for two years past. One runs from the Place Royale to the end of the Rue Beliard and the other is in the Parc au Rond-Point. Each line is about 2¼ miles long, and each car makes 12 round trips per day. The weight of one car and 30 passengers is 15,200lb. in total. The accumulators number 100 of the Julien system; and these are mounted either 100 in tension, or 50 in tension and 2 in quantity. There are two sets of accumulators so that they may be exchanged, and each set has an electric energy capacity of 31 miles as a maximum. Each battery weighs 3,300lb. The station plant includes a main motor of 150 h.p. driving four dynamos, each giving 200 to 500 volts.

Hamburg Tramway.—This was built by the same company as that at Brussels, and differs little from that one in detail. It runs from Rathhausmarkt to Bambek. As at

Digitized by Google

Brussels, the carriage complete, with 32 passengers, weighs 10,120lb., and the battery of 100 Julien elements weighs 3,300lb. The transmission of power is accomplished by belts, intermediate axle, and sprocket wheels and chains. The speed of the motor is regular, and varies with the manner of putting the accumulators in circuit. There are likewise two sets of batteries, each having a capacity of thirty-one miles. Each car runs about sixty-two miles in total per day.

Newcoves Tramway.—This line is 1·97 miles long, with gradients of 30 and 40 per cent. The motor car, which in case of need can haul a second lighter car, has a net weight of 6,160lb. The transmission is by the Lichterfelde system of steel cords; and this apparatus, with the 10 h.p. motor, weighs 1,100lb. The car will carry thirty passengers. Each set of batteries weighs 3,300lb., and the total weight to be hauled is about 14,000lb. The average speed of the car is 7·8 miles per hour. Each vehicle makes ten round trips daily.

The following table sums up the different typical lines:

(1) Traction of train by locomotive (New York and Minneapolis).
(2) ,, by transmission of energy by cables (Frankfort).
(3) ,, ,, by cables with steep grades (Moedling).
(4) ,, ,, ,, rails (Lichterfelde).
(5) ,, ,, ,, ,, (Brighton).
(6) ,, Tatham accumulators (Rochdale).
(7) ,, Julion ,, (Brussels, Hamburg).
(8) ,, Green ,, (Newcoves).
(9) ,, Copper ,, (experimental on paper).

The author's conclusions are thus given:

(1) *Traction by Transport of Energy.*—There is no sensible difference between the use as a conductor of the aerial cable or the rail. The work performed by the machine generating the initial force, with dynamos generating electricity, being assumed as 100, the loss by transmission of force from engine to dynamo is at least 30 per cent. The electric energy sent by the dynamo to the electric motor on the vehicle will be about $100 \times 0{\cdot}70 = 70$; the loss by transport is about 40 per cent. With these two assumptions the motor will only then receive $70 \times 0{\cdot}60 = 42$. The transformation of this electric energy into mechanical work will occasion a new loss of effect of at least 28 per cent.; and the driving-wheels can thus only utilise 72 per cent. of the 42 available; or, say, 30·24 of the original 100.

To summarise the above, it may be said that the driving-wheels on the car only utilise on an average:

78 per cent. of the work furnished by the motor.
40 ,, ,, of that furnished by the generating dynamo.
30 ,, ,, only of the initial force from the main engine.

(2.) *Traction by Accumulators*—Assuming, as before, 100 as the work done by the engine generating the initial force, the average loss in transmitting this force to the generating dynamo is 30 per cent. The energy furnished by the dynamo to the accumulators is then $100 \times 0{\cdot}70 = 70$. The loss by transmission of the battery energy is 30 per cent. again, so that the motor can only dispose of $70 \times 0{\cdot}70 = 49$. To transform this electrial energy into mechanical work will bring about, as before, a further loss of 28 per cent.; so that the useful mechanical effect upon the wheels is only $49 \times 0{\cdot}72 = 35{\cdot}28$ of the original 100. To summarise as before, we have:

The driving wheels can only on the average utilise:

72 per cent. of the electric energy furnished by the motor.
50·04 ,, of that furnished by the accumulators.
35·28 ,, of the initial force from the main generating engines.

FACETIÆ.

IRISH.—It is said that the electrical officials at the Irish Exhibition have a special pass. Attendant: "Not by the turnstoiles, sorr; you go in by the entrance out."

WHAT MADE THE NOISE.—In a photographic studio where the latest innovation in the shape of an arc lamp of five thousand candle power was used to obtain the greatest artistic effect, a lady having her photograph taken enquired the cause of the occasional strong hissing noise made by the lamp. The photographer informed her that it was the carbons feeding. "I wish you would feed them before business hours, then," she replied. A fact!

THE PROTECTION OF ELECTRIC LIGHT STATIONS FROM LIGHTNING.*

BY W. J. JENKS.

Early in June a circular was issued from the Standardising Bureau office to each Edison illuminating company, asking what method of protection, if any, had been adopted and what results attended its operation. Up to Saturday night last, answers had been received from 59 central stations, demonstrating the lively interest taken in the subject and the fear of a peril little understood and possibly very difficult to guard against.

I shall have time to-night to consider only very briefly and imperfectly some possible causes of the almost unaccountable freaks of lightning flashes. In endeavouring to illustrate the more common, I shall refer to the remarkable experiments made and papers read within a few years by Prof. Hughes, and within a few months by Prof. Lodge, the latter being recently illustrated before the Society of Arts, of London.

I have shown some of the results which have been produced by a charge carried without any serious heating of a No. 12 B. and S. iron wire; also the prodigious energy expended in the twinkling of an eye by a current of suffi cient amperes to melt what was probably a poor joint or a corroded spot in a solid rod half an inch in diameter.

It is probable that, no matter how peculiar the track taken, the lightning always follows Ohm's law strictly, choosing the line of least real resistance. Several paradoxes at once appear. It is observed that in cases of burnouts of armatures the lightning spark appears to jump from one commutator bar to the shaft, and so to earth, or, perhaps, again from the shaft to an opposite bar, escaping by the conductor of opposite polarity; or, if it pierces the insulation of the coils, it usually jumps from an outside wire nearly midway of the length through intervening layers, straight to the core or shaft, but without following the wire through a circuitous route. This is shown graphically in the sketches, Figs. 1, 2, and 3—the first showing the armature construction, the second a relay, say, of five ohms, shunted by an air space of $\frac{1}{8}$in., and the third a loop of heavy copper, its ends close together. All embody the same idea, that of the enormous increase of the resistance offered by a conductor to the passage of a current through electrical inertia or self-induction.

Water in a pipe cannot be started into rapid motion in an instant. A very quick and violent blow upon the water may burst the pipe, but will not propel the water. If you apply enormous power suddenly to the piston of an engine having a driving pulley weighing several tons, you may break some portion of the machine, but the inertia of the wheel must be gradually overcome. So it is with a rush of such inconceivable velocity as lightning, for we must remember that practically, and for aught we know absolutely, the E.M.F. of any electrical flow is simply its velocity, and a tension of 1,000,000 volts means that the impulse is toward a velocity 1,000,000 times as great as with one volt. The flash occurs, and with such suddenness that the metallic particles cannot adjust themselves to transmit the motion as quickly or as easily as a narrow air space. Hence, while the resistance offered by a heavy copper loop to a current of low velocity is as nothing, its resistance to a momentary discharge of very high velocity may be beyond our power to compute, and a side flash takes place to any available conductor.

Again, let us consider the stored energy of a highly-charged thunder-cloud as analogous to the pent-up forces of a steam-boiler at high pressure. Liberate either and rapid motion results. The energy of each can be expended only in one way—namely, as arrested motion, and the energy of arrested motion always appears as heat. If we give the steam a broad free opening, its velocity of expansion is frightful, and after the first impulse it recoils and surges and oscillates back and forth until its energy is dissipated. If the opening be small and the friction of the discharge be great the high pressure of the minute jet will be gone by the time it meets the outer air. So with the electric discharge. The outburst of great velocity recoils along the

*Abstract of paper read before the Association of Edison Companies.

Digitized by Google

conductor and oscillates back and forth until its pressure has gone into heat and equilibrium is reached. There may be millions of these oscillations in a second, for they all take place within the $\frac{1}{100000}$ of a second, which represents the duration of the discharge.

One more surprising thing has been developed from the theory of Clerk-Maxwell by Prof. Hughes, Lord Rayleigh, and others, and clearly stated by Prof. Lodge. It is that when a current starts in a conductor it begins on the outside, and gradually, though rapidly, penetrates to the interior. A steady or direct current, once started, flows uniformly through the whole section of a conductor; an oscillating or alternating current does not. It is started first at the surface, and it is stopped there first. With rapid alternations, then, lightning cannot penetrate below the skin, as it were, of the conductor. In this outer skin of microscopic thickness electricity may be oscillating while the interior is idle, and the real conducting substance is confined to the surface. This is a fact distinct from the old one, that static charges dwell only on the surface.

In Prof. Lodge's experiments with a constant E.M.F. and with resistances, explained in his lectures to the Society of Arts, the distances which sparks would jump were shown.

Two surprising hindrances are apparent, the electrical inertia, which does not act as resistance, by using up energy and radiating heat, but causes a dodging or side flash, and the similar effect of a throttling nature resulting from surface action, which does dissipate energy as heat. These combine their forces to resist the passage of lightning along the best of conductors.

How, then, may we best guard against this, until recently, unsuspected effect?

1. By making the conductor in the form of a ribbon instead of a rod. This advantage can be approximated by using strands of fine wires. Experiments show very little difference with conductors of small size, so far as melting with large currents is concerned, but this is not the point. With lightning there can be no time for surface cooling. If the conductor has literally too much current to carry it will melt instantly, no matter what its surface as compared with its mass. The difference between a tape and a rod is shown to be at least 25 per cent.

2. By making it of iron in preference to all other metals. It may be objected that iron has more self-induction than copper; that is, a current going through iron has to magnetise it in concentric layers, and this takes time and develops inertia.

It appears likely that the alternations are too quick to magnetise the iron, or the current operates so entirely on the surface that there is nothing to magnetise; at all events, a coil made of tin-foil requires the same E.M.F. to give the same length of spark when it is placed in the circuit of a Leyden jar discharge, whether it has a bundle of fine iron wires as a core or not.

Even with these precautions, side flashing and jumping from the rod cannot be entirely stopped. No matter if it be made a foot or a yard wide, the increasing of resistance in a side path serves not to stop the flashing, but only to weaken it.

3. One more remedy suggests itself, viz., giving the conductor as much capacity as possible. Such a condenser as Mr. Edison suggests provides a very large surface for interchange, a storage ground, as it were, where the energy can be momentarily accumulated by charging up the plates, and the violence of the disruptive spark somewhat broken. If by any means we can thus slow down the velocity of the discharge, we avoid much of the danger of the side flash, which punctures our armatures, and allows the line current to follow and melt them.

In this connection a most interesting diagram may be briefly explained. When a gradual charging has taken place, and a ground wire or rod is awaiting the flash from the cloud, we have an effect which may be described as "steady strain." Experiment shows that a flash will jump three times as much air and encounter a megohm resistance rather than take the short direct path offered by the equivalent of a large knob (about two and a quarter times as large in diameter as the smaller one). If we interpose into one of the conductors a resistance, equivalent to a bad ground connection, we find that up to a certain point the worse a conductor is, the quieter (and less explosive) will be the flash (while the energy or heating effect remains substantially the same), and the protection, if the current is led to the right spot, will be as good. The potential which has to be absorbed or used up, is expended more gradually.

But often the clouds spark first into one another, and then as a sort of recoil into the earth. An upper may spark to a lower, and instantly this overflows into the earth, and the conductors previously uncharged do not have time to prepare any carefully-chosen path by induction. This is a sudden rush, and the effect is radically different. The best and highest conductors will be struck with equal ease, no matter what their shape or size, and probably all three will be struck at once. Now insert resistance into one and its protective power disappears. It may even penetrate the cloud, but it assists very little, if any, in discharging it. So a bad ground cannot protect against these explosive discharges.

Where a bolt strikes a system and discharges at the central station, it rushes to the ends of the system, for instance, to the open-ended conductors, such as spur mains, brings up with a tremendous water-hammer action, surges back like water in a pipe, and thus expends an enormous amount of energy before it settles to an equilibrium. Hence complaints are frequent that these long spur mains especially have lamps exploded, plugs fused, insulating joints punctured, and flexible cords short-circuited by lightning. Imagine a rubber hose, somewhat elastic, pumped very full of water, and its ends closed with spring valves. If one end is suddenly opened and as suddenly shut, a pulsation or recoil is sent back which may force open the valve at the farther end and let some water escape. Thus the electricity, when a flash strikes the lines, goes rushing and surging about everywhere for no apparent reason, just as water surges about in a canal, splashing and overflowing its banks when rocks are dropped in. Bell-wires, gas-pipes, gutters, chains, bars and bolts take side flashes from the main conductors in a most bewildering fashion; thus gas ignites in most unheard-of places, and passengers in a train may feel a shock because a charge has struck the rails. Even the hinge of a door or an isolated nail may call a spark from nobody knows where. This manifestation of electrical inertia may even cause a secondary flash from the distant end of a conductor longer than the original spark, and the reason for what we are accustomed to regard as return strokes thus becomes plain.

Three kinds of damage may be said to be done to our electric light systems by lightning discharges:

I. Disruptive damage, or the expanding and explosive violence.

II. Melting or fusion by heat of the current or the arrested motion, which we may term the result of electric inertia.

III. By breaking down the insulation of apparatus, lines and fixtures, and establishing a bridge of vapourised metal or heated gas, which is followed up by the working current of the system. When a very good conductor is provided, except at a very few points, the disruptive or explosive action is commonly manifested at these intervals. When the general track of the tension resulting in a discharge is one of very great resistance, the flash appears slower and the heating effect is more pronounced.

Some of these effects have taxed the ingenuity of the brightest theorists in this field. A recent writer thus aptly expresses it: "When conductors fail it is customary to say that they are not properly made, or that there was a faulty joint, or that there was a bad earth. A bad earth is the favourite excuse. A good earth is a good thing undoubtedly, and one cannot well have too much of it, but for the flash to leave a fine thick copper conductor on a pole or chimney while still high up, knocking holes in the brick in order to make use of the soot or the smoke, or some bolts, or other miserable conductors of that sort, because it is not satisfied with the moderate allowance of earth provided for it at the bottom, is evidence either of simple perverseness, or else of something more deep-seated. If the earth is bad, the flash may show its disgust when it gets there by tossing it about and boring

Digitized by Google

holes into it, and breaking the water and gas mains. But at least it might leave the top and middle of the chimney alone, and wait until it got to the badly-conducting place before doing the damage. It is supposed with one breath to strike the conductor because it affords an easy path to earth; and with the next it is said to leave the conductor because, after all, it finds it a bad one. Besides, it need not be so very particular about a little resistance. It has already come through, say, half a mile of clear air, and we may suppose that it might manage a few feet of dry soil. It is not possible to have too much good earth except on the score of expense. But even if it were so good an earth that it may be almost called a heaven, it would not stop the tendency to 'side flash.'"

A ground connection is desirable to prevent damage to pipes, foundations and everything buried therein, but so far as getting rid of the flash is concerned it ought to suffice if the conductor was cut off level with, or even a foot or two above, the proper locality on the ground.

To sum up regarding the construction of conductors for the protection of chimneys, station buildings, and lofty poles: First, the upper end of the conductors should be pointed. It is a fact that anything will act as a point when the potential has become sufficiently high, but the object of all lightning protection is to keep down this dangerous tension wherever possible. Sharp points will radiate energy rapidly and reduce the strain far below the sparking point. One point at the top of the rod is not sufficient to insure the best results. It may become blunted by a discharge, or tarnished. The best points are cones of copper not so sharp as to be readily fused, and heavily gilded to keep them always right.

Three forms of rods have been widely produced and each quite generally adopted—viz., the round bar of copper or iron, the rope or stranded metal, and the ribbon. The English Lighning Rod Conference of 1882 gave the preference to copper tape, which is easily handled, flexible, and free from joints. The rod should not be readily corroded; allowance should be made for expansion and contraction. With copper rods the expansion and contraction with the extremes of temperature in this country is due to a variation of at least 125° Fahr., and allowance should be made of at least $\frac{1}{100}$ of the length, or an inch for every 40ft. If bends are made sharp, lightning will be apt to jump across instead of going round the bend. Flexibility is convenient, but should not be too much relied upon, inasmuch as a straight track to earth is one of the most desirable features of the main leaders of a rodded system. If lightning is led to jump across instead of coming through the entire length of the conductor, melting will probably take place, and any sparking between the upper ends of the rod and the ground connection is always a serious danger. The main difficulty with poor joints is the tremendous heat developed, with the liability of fire communicating to any combustible material.

(To be continued.)

TELEPHONIC DEVELOPMENT.

[The following article from the *Financial News* treats on an important subject, and is stated to be a special report by one thoroughly conversant with the subject.—ED. *E. E.*]

Agreeably to your request, I have examined the various systems of telephonic communication in use in England and Scotland. I have treated the three great representative centres—viz., London, Manchester and district, and Glasgow and district—separately, and compared them with each other. I have looked at the subject from a technical point of view, but, as far as possible, treated it in popular language, the intention being that your readers should be enabled to judge of the relative merits of the companies concerned—viz., the United, the Lancashire and Cheshire, and the National—and of their management.

Beginning in the North, I examined first the National Company's system. This company has now in Glasgow 1,570 subscribers. The wires converge into six central exchanges, which are connected with each other by means of from eight to 25 junction wires. The wires are entirely silicium bronze of No. 18 gauge. This wire weighs only 35lb. to the mile, against 220lb. per mile in the case of the old Post Office wires and the telephone wires commonly seen in London. The wire has the peculiar quality of returning to its normal position immediately after the snow or frost has melted off, and it contracts or expands but slightly through the action of cold or heat. Being very thin, it collects little snow, and owing to its lightness can, if broken, do little or no damage in falling. The wires are carried over the housetops by means of iron poles which rest in sockets on the roofs, and are supported by stays of twisted galvanised wire. On the principal routes five iron poles, with arms stretching across, after the pattern of a gridiron, are used. Thirty-two wires are fixed on each cross-bar, so that the five iron poles carry nearly 1,000 wires. As the distance from the exchange increases, and the number of wires becomes less, the poles are reduced to two with 30 cross-arms carrying 10 wires each. Further on, still, a single pole with 20 cross-arms carries upwards of 100 wires. The wires are attached to the arms by means of single porcelain insulators, and every joint is soldered. The use of these insulators and the soldering of the joints is of much value in producing good talking. In this connection it may be mentioned that every earth connection is also taken, regardless of distance, to the nearest water-pipe and there soldered. The intercommunication, or "switching," is accomplished in the central offices by means of the so-called "multiple" board system.

Your readers are no doubt aware that a certain number of subscribers in every telephonic exchange is allocated to each of the operators in the central offices. The wires of these subscribers are all collected upon one "table," by which means they are grouped under the control of this operator. The advantage of the "multiple" board system is that, while under the old plan great difficulty was found in practice in joining wires from table to table—that is to say, connecting with each other the groups worked by the various operators—under the new plan each wire has a connecting wire to each other wire on each table. It is difficult to convey on paper a clear idea of how this is done. The plan, though effective, is very costly, a multiple board capable of carrying 2,000 subscribers' wires requiring 400,000ft. of these connecting wires. Great quickness in service results, however, as every operator has under direct control a branch wire to the wire of every other subscriber in the central exchange. All the ringing from the exchange is accomplished by means of magneto-electric generators worked by a small turbine, the power for which is got from the ordinary water mains. Each operator has a key or switch connected with this ringing apparatus, and can thus use the currents at will upon any line required. One operator is found to be able to attend in Glasgow to about 60 subscribers. As regards the subscribers' end of the wire, each subscriber is provided with a magneto ringing apparatus for the purpose of attracting the attention of the operator. The old and costly system of ringing by means of batteries has been entirely discarded.

There is no special contrivance in Glasgow by which a subscriber can notify to the operator that his conversation is at an end. In Dundee the company has adopted a system which enables every subscriber to put himself at once—even, say, in the middle of a conversation with another subscriber—in communication with the central office. This system works well, and has been of great benefit in promoting quick service. The vexatious delays which occur when, as is too often the case, a conversation is interrupted by the central office under the impression that the interview is over, are impossible under this system. No telephonic system can be considered complete unless it embraces some contrivance for this purpose.

Overhead cables are little used in Glasgow. In this respect Manchester, as will be seen later on, is ahead. The whole of the National Company's system, even down to the smallest exchange in a country town, is open all the year round, night and day. Glasgow is connected by means of trunk lines with all the neighbouring towns of any importance; indeed, all the principal towns in Scotland can either now, or will be able very shortly, to communicate by telephone with each other.

The Manchester telephonic exchange system differs in many ways from that of Glasgow. There are 1,350 subscribers, and the whole of their wires have been concentrated in one central exchange. The wires, which are hard-drawn copper of No. 18 gauge, are carried over the housetops by means of wooden standards, with two poles and ten cross-arms, each supporting fifteen wires. On the routes requiring fewer wires single wooden poles, with ten wooden arms carrying eight wires each, are used. Single and double shackles insulate the wires. Glover's anti-induction 20-wire cable plays an important part in the outside wiring, and is found to be very successful. Along one route there is one of these lead-covered 20-wire cables one mile in length, the induction on which is said to be imperceptible. Several hundred wires are carried in this manner in many directions from the central exchange. Your readers are, no doubt, aware that it is owing to "induction" that one subscriber can overhear the conversations of another. Hence the importance of avoiding it in telephone work.

The multiple board has been introduced in Manchester with good results. The ringing from the exchange is accomplished both by means of magneto-electric machines driven by water power

Digitized by Google

and also by means of batteries. A most convenient test-board receives all the wires as they come in from the roof. It is arranged so that by inserting a small plug the wire is disconnected either on entering or leaving the test-board. By this means all the wires can be at once tested, and if not found to be in working order they can be repaired, it may be before the subscriber has discovered the fault. All the neighbouring towns of Lancashire and Cheshire are connected to Manchester by means of trunk lines. A special charge is made for each conversation on these trunk lines, and monthly accounts for these charges are rendered to each subscriber. In order to prevent disputes the particulars of these connections are written on a slip of paper, and this slip is placed in a small machine, which stamps on it the date and the time to a minute. Three operators attend to 200 subscribers.

A special feature of the Cheshire Company's system is the use of what are called "polarised indicators." I can only hope to explain the effect of these to your readers, an idea of the mechanism not being easily conveyed. To attract the attention of the central office, each subscriber has a battery of four cells, which is put in action by one of two push buttons—the one white and the other black. The white button sends a current which calls the attention of the operator in the usual way, thus notifying that the subscriber desires to be connected with some other subscriber. The operator having placed him in communication and his conversation being over, by means of the black button he is enabled to notify that the conversation is at an end, and in any case to make it clear in the central office that it is to them, if to anyone, he desires to speak. In other words, he has a similar advantage in this respect to the National Company's subscribers in Dundee. But this is gained at greater expense to the company, as the apparatus and accessories are costly and liable to get out of order.

It now remains to consider the London system, where there are now upwards of 4,800 subscribers to the United Telephone Company's exchanges. The wires are concentrated into some 20 different centres, about half of which have between 100 to 600 subscribers each, the rest having a small number. The largest exchange is in Coleman-street, where there are about 500 wires. Hard-drawn copper wires are now being used on new work, but the bulk of the work has been done with steel wire of No. 8 gauge, and where the largest numbes of wires converge they are attached to massive angle iron tower-shaped fixtures by means of single shackles. From each corner of these fixtures two sets of upwards of 50 wires each are led off in opposite directions. Thus each of these important fixtures are designed to carry only about 400 wires. The main routes are conducted over the house-tops by means of single iron poles, each having twisted wire stays to support it. The wires are arranged in one row, say, of 20 to 30 wires, reaching in a line from top to bottom of the poles, and are attached by clips and double shackles. Overhead cables are very much used, upwards of 25 of these leading away from the central City exchange. In three or more of the principle centrals multiple boards have been introduced, but in all the rest the original single-wire system remains. This, of course, entails delay, and is the cause of many of the instances of bad service which occur. The exchanges have hitherto been closed at nights and on Sundays, and are now only open in part for a continuous service. The subscribers to the London system use the original form of electrical ringing apparatus, operated by a battery—there is no separate arrangement for ringing off or calling the central office, and, in fact, no improvement of any kind has been introduced in this connection since the beginning. There has hitherto been no system of public call offices, and with the exception of Brighton and Tilbury, no towns are connected to London by telephone. The Tilbury wire is practically disused, and the Brighton wire has been so inefficient as to lead to no practical benefit. As regards trunk wires, in fact, London may be said to be quite isolated.

Having thus described shortly the representative centres of British telephony, and stated the plain facts in each case, let me make a short comparison of the results obtained by the companies. The question first of all arises, is it wise to concentrate all your wires into one central, as in Manchester, or to have many exchanges, as in Glasgow and London? Under existing circumstances, and unless some better system of inter-switching between exchanges can be introduced, Manchester takes the lead. It must be admitted that the expense of concentrating is very great; but still, in telephony, it is pre-eminently the case that the best service, although costly, is the one that will eventually pay the best. Then as to the wires, Glasgow and Manchester undoubtedly lead the way with silicium bronze and hard-drawn copper wires of a small gauge, which are better conductors, last longer, and exert only one-sixth of the strain resulting from the old-fashioned steel or iron wires so much in use in London. The next point is the fixtures on which the wires are carried. London again is found behindhand, for while Glasgow and Manchester carry from 100 to 300 wires on each main route, London *with practically, as regards wayleaves, the same outlay carries only 20 to 30.* The large angle-iron central standards are undoubtedly substantial, and even artistic in design, but quite unsuited for the purpose, while the only parts of the structures themselves which could conveniently and economically be used for carrying wires—viz., the flat sides—are not made use of at all!

In the manner of the attachment of the wires to the fixtures Glasgow stands first. Single insulators, as there invariably used, have eight times the insulation resistance of the double shackle of Manchester and London, and correspondingly good talking power. In cables Glasgow is left behind.

Descending to the switching-rooms, Glasgow and Manchester are on a level footing, whilst London is just awakening to the fact that improvements upon original types exist. Manchester and Glasgow have long had an all-night and Sunday service, while London has only just begun to follow them in this. With regard to the ringing-up systems with which subscribers are provided, undoubtedly the magneto system of Glasgow is the cheapest and most efficient. Still, Manchester, with the white and black buttons, has a great advantage. The London electrical ringing system is at once the most expensive and the least efficient, and has not even the redeeming feature of a special ring-off system, as in Manchester. In the matter of trunk lines, Glasgow and Manchester have been at work in earnest, while London has done in effect nothing.

With regard to the practical working, it may be stated generally that London is not to be compared with the others. The causes of the delays, the induction or leakage, and the continual disconnection during conversation, which renders the telephone in London comparatively useless, are to be found in the defects of the system, which, as I have shown, is in every point inferior to that in other centres.

CITY NOTES.

Brazilian Submarine Telegraph Company.—The traffic receipts of the Brazilian Submarine Telegraph Company, Limited, for the week ended August 24 amounted to £5,229.

Dissolution of Partnership.—Mr. H. E. Harrison, having retired from the firm of Phillips, Harrison and Hart, electrical engineers, of Westminster, the business will in future be carried on by Messrs. Phillips and Hart.

West African Telegraph Company.—The half-year's interest, due September 1, upon the five per cent debentures of the West African Telegraph Company, Limited, will be paid at the National Bank of Scotland, Nicholas-lane, on and after that date.

Western and Brazilian Telegraph Company.—The traffic receipts of the Western and Brazilian Telegraph Company, Limited, after deducting the "fifth" of the gross receipts payable to the London Platino-Brazilian Telegraph Company, for the past week was £4,367.

Lancashire and Cheshire Telephonic Exchange Company.—The report of the Lancashire and Cheshire Telephonic Exchange Company, Limited, states that the subscriptions and rentals (including those of the out-districts) pertaining to the financial year, ended June 30, amounted to £89,797, as compared with £82,490, the amount of income carried forward as representing sums received in advance for periods extending beyond June 30 last being £40,377, against £38,276. The Directors recommend a further dividend at the same rate as in February, making a complete dividend of 7 per cent. for the year, leaving a balance of £5,420, of which they propose that £3,000 be placed to the reserve fund (making a total reserve, including interest, of £8,650), and that £2,420 be carried forward.

PROVISIONAL PATENTS, 1888.

AUGUST 17.

11,897. **Electrical indicators.** Oliver B. Shallenberger, Rochester, Pennsylvania, United States, or William Phillips Thompson, as a communication from George Westinghouse. (Complete specification.) (Date applied for under Section 103 of the Patents, &c., Act, 1883, 21st January, 1888.)

11,898. **Electrical indicators.** Oliver B. Shallenberger, Rochester, Pennsylvania, United States, or William Phillips Thompson, as a communication from George Westinghouse. (Complete specification.) (Date applied for under Section 103 of the Patents, &c., Act, 1883, 21st January, 1888.)

11,913. **Improvements in grapnels for raising submarine cables.** Francis Robert Lucas, 24, Southampton-buildings, London.

11,917. **Improvements in or connected with the transmission of electric energy.** James Grieve Lorrain, Norfolk House, Victoria Embankment, London, W.C.

11,925. **Improvements in electrical switches.** Herbert William Edlin, 53, Chancery-lane, London.

AUGUST 18.

11,929. **Improvements in electrical indicators.** Gustav Binswanger, 5, Great St. Thomas Apostle, London, E.C.

11,937. **Improvements in apparatus for driving dynamos and similar machines for electrical purposes.** Frederick Charles Lynde, 48, King-street, Manchester.

Digitized by Google

11,939. **A new non-magnetic metallic alloy.** Heinrich Ostermann and Axel Prip, 68, Fleet-street, London. (Complete specification.) (Date applied for under Section 103 of the Patents, &c., Act, 1883, 16th February, 1888.)

11,941. **A new non-magnetic metallic alloy.** Heinrich Ostermann and Charles Lacroix, 68, Fleet-street, London. (Complete specification.) (Date applied for under Section 103 of the Patents, &c., Act, 1883, 25th April, 1888.)

11,963. **Improvements in or connected with electric rail or tramway systems.** Michael Holroyd Smith, 55 and 56, Chancery-lane, Middlesex.

11,965. **Improvements in anti-induction electric apparatus.** Jules Cerpaux, Pierre Borre and Léon Maertens, 33, Chancery-lane, London.

AUGUST 20.

12,010. **Electric signal lantern.** C. F. Emanuel Berg, 20, Johannes Strasse, Berlin. (The firm of Keiser and Schmidt, Berlin.)

AUGUST 21.

12,054. **Improved means for diminishing the injurious effects of induction currents in telegraphic and telephonic circuits.** E. Liebert and Sally Adolf Rosenthal, 45, Southampton-buildings, London.

12,063. **Improvements in or relating to electrical type-writers.** Alfred Julius Boult, 323, High Holborn, Middlesex. (James Francis McLaughlin, United States.) (Complete specification.)

12,064. **Improvements in or relating to electrical type-writers.** Alfred Julius Boult, 323, High Holborn, Middlesex. (James Francis McLaughlin, United States.) (Complete specification.)

12,065. **Improvements in or relating to electrical type-writers.** Alfred Julius Boult, 323, High Holborn, Middlesex. (James Francis McLaughlin, United States.) (Complete specification.)

12,066. **Improvements in or relating to electrical type-writers.** Alfred Julius Boult, 323, High Holborn, Middlesex. (James Francis McLaughlin, United States.) (Complete specification.)

AUGUST 22.

12,126. **Improvements in and relating to merry-go-rounds and the like, and in apparatus and devices in connection therewith, propelled and operated by means of an electric current.** Richard Richardson Hutchinson, 4, Little Moorfields, E.C.

12,127. **Improvements in and relating to electric motors.** James Feaveryear, 4, Little Moorfields, E.C.

12,129. **Improvements in automatic electric signalling for railways.** John Leman Eckersley Daniel, 68, Fleet-street, London.

AUGUST 23.

12,149. **An improved electric battery.** James Hargreaves and James Croft Sewell, 4, Clayton-square, Liverpool.

12,155. **A new or improved application of electricity to the manufacture of soap.** Robert Scott and Charles Richard Held, Market-place, Huddersfield.

12,157. **Improvements in portable electric lamps with combinations.** John Samuel Ross, 72, Hammersmith-road, West Kensington, Middlesex.

12,158. **Improvements in working railways by electricity.** Charles Ernest Spagnoletti, 21, Cockspur-street, London, S.W.

12,163. **Improved cell or containing vessel for electric batteries.** Henri Georges Charles Serrin, 46, Lincoln's-inn-fields, London, W.C.

COMPLETE SPECIFICATIONS ACCEPTED.

AUGUST 24, 1887.

11,543. **Improvements in electrodes for electric accumulators or secondary batteries.** Henry Tudor, 6, Lord-street, Liverpool.

SEPTEMBER 13, 1887.

12,414. **Improvements in electric arc lamps.** Frederick Carrington Phillips and Hugh Erat Harrison, 2, Victoria Mansions, Victoria-street, Westminster, S.W.

SEPTEMBER 20, 1887.

12,763. **Improvements in electric meters, or apparatus for measuring electricity.** George Forbes, 34, Great George-street, Westminster.

OCTOBER 13, 1887.

13,853. **Improvements in and connected with telegraphic apparatus for transmitting orders, or other communications.** George Alexander Calvert, 87, St. Vincent-street, Glasgow.

OCTOBER 14, 1887.

13,978. **Improvements in electric firing gear for rapid firing and other guns.** Andrew Noble, Jesmonddene House, Newcastle-on-Tyne.

OCTOBER 24, 1887.

14,416. **Improvements in telephonic apparatus.** John Lorimer Corbett, 62, St. Vincent-street, Glasgow.

NOVEMBER 2, 1887.

14,954. **Improvements in apparatus to be used in the deposition or treatment of metals by the electrolytic process.** William Terrill, 55 and 56, Chancery-lane, Middlesex.

JUNE 12, 1888.

8637. **Improvements in electric clocks.** Albert Lyman Parcelle, Boston, Massachusetts, United States.

JULY 23, 1888.

10,631. **Improvements in electrical night-signalling apparatus.** Emil Kaselowsky, 6, Bream's-buildings, London.

SPECIFICATIONS PUBLISHED.

1887.

10,200. **Dynamo-electric generators and motors.** H. C. Bull and Co, and H. C. Bull. 8d.

12,823. **Telephonic arrangements, &c.** A. A. Campbell-Swinton. 8d.

13,207. **Indicators for electric bells.** A. Morley and H. W. Wilson. 8d.

13,221. **Controlling automatically armatures, &c.** J. H. Holmes. 8d.

13,333. **Secondary generators, &c., of electricity.** J. D. Gibbs and E. Fesquet. 8d.

13,338. **Electric lamp attachments.** W. Hartnell. 8d.

1888.

4759. **Telephonic apparatus.** H. H. Lake (International Dudley Signal Co.) 1s. 3d.

9332. **Electrical connection of railroad rails.** F. Stitzel and C. Weinedel. 6d.

NOTES.

Cable or Electric.—Electric cars can be worked on gradients up to 10 per cent. Anything over this is the right place for a cable system.

Turin Theatres.—The authorities at Turin have issued notices that all theatres not lighted by electric light by the 1st of November will be closed.

Lightning Arresters.—The Thomson-Houston Company always use lightning arresters in their tramcar motors. Several motors of other companies have been burnt out.

Unter den Linden.—On Thursday August 30th the magnificent street of Berlin, Unter den Linden, was lighted for the first time by electric light. The effect was very fine.

Thomson-Houston v. American Co.—A cablegram this week states that a judge's order has been granted restraining the American Co. (Fuller-Wood) from sale or shipment to England.

Whitworth Scholarship.—Mr. B. Young, 23, electrical-engineer apprentice, Belfast, has obtained a Whitworth exhibition, tenable for one year, of the value of £100, and also a Royal exhibition.

Electric Roads in Great Demand.—It is a very small and lifeless town in the west of America that is not now agitating the establishment of an electric street railway, says the *Western Electrician*.

Chatham.—The local electric lighting company have this week been busily engaged in putting up wires in High-street, Chatham. The circuit is now almost complete, and lighting will be commenced in a few days.

Telegraph Trust.—A rumour is afloat that a gigantic telegraph trust will be formed on the other side of the Atlantic. Jay Gould proposes to sell out his interests to a syndicate composed of the owners of the cable companies.

Bridlington Quay.—At the Local Board meeting on Wednesday, the question of lighting the Sea-wall Parade with electric light was brought forward, and a resolution passed instructing the committee to ascertain upon what terms it could be done.

Bath.—The Bath Gas Company, stimulated by the recent decision in favour of electric lighting, has decided at their own expense to fix some improved lamps to show what they can do when put to it. The electrical engineers, however, are not despondent.

Sea Telegraphy.—Wanted, an inventor to devise a practical apparatus for ships whose indicator shows whenever the ship approaches another vessel carrying a similar apparatus. A practical marine signalling apparatus of this description would have a wide application, and save many lives and much money.

The Hall Electric Pump.—Referring to the Hall electric pump, illustrated on page 544 of our issue of June 8, Messrs. Woodhouse and Rawson inform us that they are now in a position to quote for supply of this pump in England, and the prices and description will be inserted in the list now preparing.

Death of Dr. Clausius.—The eminent professor of the Bonn University, Dr. Clausius, died on the 24th of August. He was born in Pomerania in 1822, and attained world-wide celebrity as the demonstrator of the mechanical theory of heat. Among purely scientific men few are more honoured than the famous Professor of Natural Philosophy.

Railway Induction Telegraph.—The telegraph departments of the Union Pacific and the Western Union are going to give a trial to the system of telegraphing to trains in motion adopted on the Lehigh Valley roads. There is probably a good paying line in this direction for our railway electrical engineers to take up in this county.

Found Dead.—A man and his wife were lately found dead in Chicago. The man had hung himself, but there was no indication of the manner of his wife's death. It is thought that the wife was killed with an overdose from a powerful magneto machine that they were in the habit of using, which was on the premises, and that the husband, fearing consequences, committed suicide.

Suspended Electric Railway.—The novel electric tramway we described lately is to be put in practice at St. Paul, Minnesota. The railroad is an elevated structure, and the cars are hung below it close to the street level, and take their power from the overhead wheels. It may be said to be a kind of passenger telpher line. The speed claimed is from eight to ten miles an hour.

Mineral Wool Regulator.—An invention for the regulation of electric circuits has been patented in America by Messrs. J. Vansant and Frank Anderson. This consists of a variable resistance composed of carbon and mineral wool which can be compressed in the containing receptacle by the means of adjusting screws, thereby diminishing or increasing the strength of the current.

Paris Time.—The French Government have decided that at the inauguration of the Paris Exposition one uniform time for the whole of France, to be called *l'heure nationale*, will be put in force, instead of the three systems at present in use. It will be communicated electrically from Paris, and will be adopted at all railway and public buildings. Both the French and the foreign hours will be marked at the frontiers.

Exeter Theatre.—Exeter Theatre! What painful reflections these words call up. What oceans of good advice, and heaps of suggestions, were made at the time of the disaster. One of the most practical of these suggestions at any rate will shortly be carried into effect, and the electric light will illuminate in beauty and safety the projected new building in Longbrook-street. A sum will be specially set aside for this purpose

Melbourne.—The alternating plant for 100,000 lights, on the Zipernowski-Deri system, for Melbourne, is being installed by Mr. Charles Flesch, who controls the patents in Australia. He also expects to have a plant of 1,000 arc lights in the coming autumn exhibition. After extended investigation Mr. Flesch has selected the Westinghouse meter as the best in Europe or America, and has given an initial order for 500 meters.

The Hochhausen.—Our old friend, the Hochhausen dynamo, is cropping up again in America, and is being worked by the Excelsior Company of New York. We thought we recognised the old cut of the machine; but what about the description of it?—"The *only* system in the world capable of working arc and incandescent lights on the same circuit successfully!" Pretty good that for Munch—— beg pardon, Hochhausen.

C. and C. Motors.—As many as 300 C. and C. motors are in practical use in New York, distributed in 115 installations. Of these motors 260 are ⅛ h.p., eight of ¼, 19 of ½, six of one, two of two, one of three, and two of five. They are running on the Edison, Brush, and other circuits. They are wound for either arc or incandescent circuits, and

Digitized by Google

are used for sorts of small work. Messrs. Shippey Brothers are the agents for Great Britain and France.

Ammeter for Minute Currents.—A galvanometer for the direct measurement of very small currents is shown by Mourlon, of Brussels, at the Brussels Exhibition. It will probably be most useful to medical practitioners in electrical treatment who require to measure currents of a small amount. The instrument indicates directly, and without oscillations, currents from one 1,000th up to one ampere. A resistance of sulphate of zinc and water completes the apparatus, which is handsomely mounted.

New Filaments.—Mr. Shippey has patented a new filament, prepared from semi-metallic material, which he claims is free from the previous patents. Another part of the patent consists in a method employed by him of using up old or damaged filaments. Instead of being useless, as heretofore supposed, Mr. Shippey states that old filaments, being of very pure carbon from the continued action of the current, can be pulverised and remade into filaments, making a better quality of filament than the original.

Hiring Out the Power. — Mr. Spaulding, of the motor department of the Thomson-Houston Company, gives one instance of an electric car company who have an installation of electric power circuits in conjunction with their own tramway system. The company is paying all the running expenses of the road out of the profits of the stationary power system, and has the whole of the income from passengers a clear source of profit to the company. Intending installers of electric roads had better bear this in mind.

Office Lighting.—The electric light is making good headway in London offices. Some thousands of lamps are already in use from isolated plants, and we learn that Messrs. Drake and Gorham, who are responsible for the greater part of these installations, and have made a specialty of this class of work, have recently been entrusted with the lighting of Messrs. Johnson, Budd and Johnson's new offices. The plant will consist of an Otto engine, Elwell-Parker latest type dynamo, and a set of 53·23 L cells made to Drake's and Gorham's specification.

Sawdust Fuel. — An electric light station in Mississippi has a sawmill close to, and experiments have proved so satisfactory in burning sawdust in the boiler furnaces that this form of fuel will be used in future. The sawdust is supplied by a large pipe of galvanised iron, 1ft. in diameter, from the sawmill to the station, and a powerful artificial draught blows the sawdust from one place to the other. The electric light company will be able to supply the sawmill with its power for nothing, in return for which it will get all its fuel gratis.

Toulouse.—Toulouse is to have an installation, where all the circumstances are exceptionally favourable. It has already had for more than a year an installation of about 800 lamps; this is driven by water power, not by gas, as has been sometimes stated. The Theatre du Capitole has a small installation run by gas-engines, but this is distinct from the town lighting, which utilises the water power of the river. The installation is to be increased until 2,000 h.p. is utilised to supply 20 to 25,000 lamps. The conditions are such as to delight the heart of the electrical engineer. The water power is in the centre of the town, permission is obtained to use overhead wires, and the plant will be in use during the whole 24 hours—for a chemical works is to be built in the vicinity, which has arranged to take all the current not required for lighting.

Electric Light for the British Association.—Prof. Ayrton, and other scientific gentlemen, visited Bath on Monday for the purpose of arranging with the secretary of the Local Committee and Mr. Massingham for the practical demonstrations of his lecture on the "Electrical Transmission of Power," to be delivered at the Drill Hall this evening. The experiments will be of the most elaborate kind, and will illustrate the application of electricity to various manufactures, driving different kinds of machinery, welding metals, &c. During the visit of the Association, Mr. Massingham will also illuminate the Sydney Gardens on three nights—including the floral fête fixtures—when there will be a grand display.—The Town Council having resolved to light a portion of the city permanently with electricity, the temporary installation which at first was intended to be laid down, will not be carried out.

Telephonic Improvements in Manchester.—At the close of the meeting of the Lancashire and Cheshire Telephone Company on Wednesday, the shareholders and subscribers and a number of other gentlemen interested in the telephonic system had an opportunity of inspecting the extensive changes which have been made at the new central office of the company in the Royal Exchange. The company, having outgrown the practical capabilities of their old system, have now adopted what is looked upon in the telephonic world as by far the best system extant—the Western Electric Company multiple switch-board. The working of the new system was explained to the visitors by the officials of the company, and illustrations of it were given by the young lady operators, of whom some thirty or forty were seen at work. The process appears somewhat complicated, but the young ladies seem to have mastered it thoroughly, and there was an entire absence of the ringing of bells and the loss of temper which are generally associated with the working of the telephone.

Electricity at the British Association.—The following are among the papers, in connection with electricity, to be read at the Bath meeting. In the Mechanical Section (G): "A Twenty-ton Travelling Crane Worked by Electricity," by Mr. W. Anderson; "Gaseous Fuel,' by Mr. J. E. Dowson; "Light Road Railways," by Mr S. P. W. Sellon; "A New Form of Edison Recorder, and Modern Developments of Graphic Methods," by Prof. N. S. Hele Shaw; "Cowles' Electric Smelting Process," by Mr. R. E. Crompton; "Electric Lighting in America," by Prof. George Forbes; "Electricity as Applied to Mining," by Mr. F. Brain; "Suez Canal Lighting," by Mr. R. P. Sellon; "Edmunds' System of Electrical Distribution from Central Stations," by Mr. N. Edmunds, and "Miners' Electric Safety Lamps," by Mr. N. Watts. A joint discussion with Section A will also take place on "Lightning Conductors." In the Physical Section (A): "On the Heating Effects of Electric Currents," by Mr. W. H. Preece, F.R.S.; "On Measurement of Electrical Wave-Lengths," by Prof. Oliver J. Lodge, F.R.S.; "The Recent Magnetic Survey of Japan," by Dr. C. G. Knott; "On the Transference of Electricity within a Solid Conductor," and "Connection between the Mathematical Theories of Electromagnetic Induction, Viscous Fluid Motion, and Equilibrium and Motion of Elastic Solids," by Sir W. Thomson, F.R.S.

Barnet.—The contract stipulating that Barnet was to be lighted by the 1st of September by electricity—by the 1st Barnet was so lighted. There has been a good deal of discussion about the light, and naturally unusual interest

Digitized by Google

is manifested at Barnet itself, where the gas company have incontinently reduced their price from 6s. to 4s. 3d. per thousand; but it is too early for us to describe the installation as it will finally appear. The posts are permanent and some of the wiring, but the delay caused at the beginning with reference to contracts has run the time very short, and at last a temporary engine and a temporary dynamo were brought and the 71 32-c.p. lamps were lighted. The lamps are placed on strong ornamental posts 12ft. in height, fitted with reflectors, by means of which the light is distributed over a large area. The electricity is conducted over the town by about five miles of bare hard-drawn copper wire. Where the wires cross the main thoroughfares, they are laid under ground in creosoted wooden troughs, insulated, and cased in lead tubes. The underground wires pass up through the lamp columns to the globes, and each column is provided with a small door, with an independent switch for each. The dynamo is run at 800 revolutions per minute. The works are at the Hadley end of High Barnet, and the company purpose laying down sufficient machinery for supplying from 1,000 to 5,000 lamps for use in private houses and places of worship.

Telegraphing 4,000 Words a Minute.—Details come from Washington of the system of machine telegraphy perfected by Mr. D. H. Craig, former manager of the Associated Press, who has devoted nineteen years to his system, and claims to be able to telegraph 2,000 words a minute each way, making a total of 4,000 words a minute. The messages are perforated by a little machine, about 8in. by 10in., called a "composer," on which a speed of fifteen to twenty words a minute can easily be obtained. The peculiarity of the machine is that simultaneously with the perforation, the machine prints every word in plain Roman letters like a type-writer. This copy can be retained while the perforated message is sent to the telegraph-office for transmission, with this advantage over ordinary manuscript, that it can be telegraphed at the rate of one to two thousand words a minute instead of the usual twenty or twenty-five of the hand-key system. The machine record is also much more accurate than the "sound" recorder. With the regular office perforator, experts can do 50 words a minute, or 3,000 an hour. The actual cost of transmitting is said to be not over one penny for transmitting 1,000 words a distance of 1,000 miles. The cost of paper to perforate and recording paper is 1½d.; the perforating can be done at the rate of 5d. per 1,000, and the same for type-writing at the receiving end—total, a shilling and a halfpenny for completing 1,000 words. Mr. Craig's apparatus is now on exhibition in a room in the Capitol at Washington.

Alternating Currents Abroad.—The plant for 100,000 lights for Melbourne is supplied by Ganz and Co., of Buda-Pesth. This is an ominous item of information for English electrical engineers. Can the electricians of our mother country not make alternating plants? Or do they not choose to cultivate this species of production for the colonial market? Time was, when any great piece of engineering was to be done in our colonies, or even in nearly all foreign lands, English invention and English enterprise were first in the field for the supply of such undertakings. And now we hear of plants supplied—here, there, everywhere—by Ganz, of Buda-Pesth. No doubt this is a good firm, and have good engineers; and, above all, are almost first in the field on such work. But are our electrical engineers going to stand tamely by and let contracts for important undertakings like this, in English-speaking lands, calmly go to Austrian firms? If a colony, or a foreign government, bethinks itself that such and such a place has water-power in plenty, and that at a certain not too great a distance a town is requiring electric light, to whom in England is it to apply for a contract to satisfactorily carry out such work? The field is great, and promises rich rewards. We are not behindhand in facilities and in organisation. We can carry out railways and build bridges, and now the time comes when we shall be asked to light towns. This is a matter which concerns the engineering credit of England as a whole, and it behoves the engineers of our special branch to make themselves ready for such work, and let people know that they are so ready. We do not want all our colonial towns to be lighted with Austrian plant. We wish them, and all workers in the field, well, but it seems that now for us is the time to be "up and doing," or the rewards of industry will not fall to our lot.

The Cockburn Cut-Outs a Success.—A really good thing when it comes out in the electrical world does not remain long before it becomes a success commercially. At any rate, this is apparently the case with the Cockburn cut-out. We have heard from time to time that Messrs. Cockburn and Day were very busy with their various patterns of cut-outs and switches, but the work has become so thick that they have become cramped in their works at Tabernacle-street, and have had to look out for larger premises where more scope for their inventive and manufacturing genius can be obtained. They have obtained premises of considerable extent at Ferdinand-street, Chalk Farm-road, having three floors of 110ft. in length by 23ft. wide, besides outer premises. These they are rapidly fitting up for carrying on and extending their business, which is spreading its arms into various allied branches of electrical fittings. We are glad to see a young firm put such go and energy into their business, which must eventually bear good fruit. Besides their speciality in cut-outs and switches, Messrs. Cockburn and Day are going in largely for torpedo work, and submarine mining and telegraphy, and other electrical appliances, and have also done a considerable amount of work in a new and compact form of Morse instrument. They have secured the work of making the instruments and fittings for the New Telephone Company, and are doing a considerable amount of work for the colonial and foreign Governments and for the Admiralty. The switches for the Bank of England—quick-break action, mounted on solid serpentine bases—were supplied, through Messrs. Drake and Gorham, by this firm, and a further order is on hand. We understand that the new Ayrton and Perry platinoid spring voltmeter, described at the Society of Telegraph-Engineers' meeting last season, will be manufactured by them.

Animal Electricity.—M. D'Arsonval's experiments, presented to the French Academy of Sciences by M. Brown-Sequard, go to show authoritatively that the contraction of animal muscles is dependent upon the surface electrical tension of the constituent protoplasmic particles. He shows conclusively, by a piece of physical apparatus, that alterations in mechanical tension result in alterations of electrical state; and he explains the nervous contraction of muscle upon the law stated by Lippman, that "the superficial mechanical tension at the surface of separation of two liquids is a function of their difference of potential." M. D'Arsonval's experiment gives a physical conception

Digitized by Google

of the muscular fibre. The apparatus consists of an elastic tube of rubber, divided off into a series of compartments by porous discs of wood or pipe-clay, upon which the rubber is firmly fastened. Each compartment contains a layer of mercury, upon which is placed a second layer of acidulated water. Each end of the tube is connected electrically with an indicating apparatus, such as the dead-beat galvanometer of Deprez-D'Arsonval. A weight is suspended at the bottom end. When the apparatus is at rest, no current is manifested; but if the weight be moved up and down, so that the tube assumes successively an elongated and a corrugated form, the galvanometer is traversed by alternating currents, the intensity of which is proportional to the number of compartments in the tube. The law of M. Lippman easily explains the phenomenon. Renvier has shown that the contractile muscle consists, in reality, of superposed layers, alternately liquid and protoplasmic. M. D'Arsonval's experiments explain several hitherto unexplained phenomena, as for instance, why electricity is the greatest excitant of animal muscle, why the nervous excitation is propagated electrically with the speed only of a liquid wave, and explains also, that animal muscle acts as an electric motor rather than a heat motor. The high rate of efficiency will be thus explained, and the heat generated in excessive exertion can be attributed to a waste product analogous to the heating of an electric motor.

The New Court Theatre of Vienna.—The first experimental lighting of the new Hofburg Theatre with electricity, says the *Times*, took place last Thursday week. Parts of the house have been lighted before, but on Aug. 31 for the first time the entire theatre—stage, auditorium, foyers, and corridors—was lighted at full power. Baron Hasenauer, the architect, Mr. T. W. Melhuish, the managing engineer, and M. Emile Sechehaye, the engineer in charge of the theatre, with about half-a-dozen other gentlemen, were the only spectators. The sight was most brilliant, and the architect, who for the first time saw in its glory the house which has taken him 13 years to build, was as much impressed as the rest of the company. The whole lighting is electric, and the arrangement is probably the most complete and substantial ever carried out in any public building. The current will be supplied on the system now known as the battery transformer system. The accumulators are situated in the cellars of the theatre, where the moat of the old Vienna fortifications used to stand, and they are charged from a central station in the Schenkenstrasse, just behind the theatre. The current is conveyed to massive regulating boards, and thence through meters to the distributing room. In this room are placed switches and automatic cut-outs governing the whole of the circuit, and going out to every portion of the house, so that any part of it can be lighted up or put in darkness as required. The total number of lamps in the house is considerably over 5,000, their candle-power varying from 10 to 40. On the stage there are 2,100 lamps of 25 c.p. each. Varied scenic effects in coloured light will be produced by tinted lamps, the coloured chemicals which have hitherto been in use for this purpose being entirely dispensed with. Throughout the house the cables and wires have either been protected by lead coverings or have been laid in wooden grooves, and the insulation of the whole has been repeatedly tested and found most satisfactory. Some changes in the distribution of light will be required before the opening. Thus, the grand staircase —one of the finest pieces of architecture in any theatre—will need more lighting, and some of the lobbies, and particularly the drawing-rooms attached to the imperial boxes, less. But already it may be said that the installation reflects the greatest credit on the company that has set it up, on Mr. H. Lindon, the energetic general inspector of the company, and on Mr. T. W. Melhuish, his very able managing engineer. The theatre is to be opened in the first fortnight in October, but the Emperor has not yet fixed the date.

Eastbourne.—At the half-yearly meeting of the Eastbourne Gas Company, held last Monday, it was decided to lower the price of gas twopence per thousand feet. The directors were unanimous in this decision, but regretted that while they gave to the Corporation a sum equal to twopence per thousand, the Corporation contemplated putting the money received from the Gas Company into the pockets of the Electric Lighting Company. They had hitherto paid £25 a year for each of the arc lights on the parade: the Electric Lighting Company now wanted £35, and the Corporation had decided to split the difference and pay £30. Thus the Gas Company took off twopence per thousand feet of gas, and the Electric Lighting Company put on £5 a year per lamp. He did not think that was quite fair; but it was eminently a ratepayers' question. This lavish outlay for electricity resulted, he thought, in no special benefit to the residents at Old Town, or the people of Meads. He knew many of the inhabitants on the Grand Parade did not like the electric light, and it was his opinion the majority of the visitors did not care a jot about it. He thought the residents on the Grand Parade should find the money, and not the inhabitants generally all over the town. However, he still hoped that the Electric Lighting Company, with the example of the Gas Company before them, would keep pace with the times, and, instead of increasing, would reduce the price of their commodity. He gleaned from a report of the Thomson-Houston electric lighting system, that some four hundred places were being supplied by that system at £22. 10s. per lamp, the light being 1,200 c.p., and the lamps being kept burning all night. Surely, if under that system electric lighting could be carried on at £22. 10s. per lamp, the Eastbourne Electric Lighting Company could supply Eastbourne at £25 a lamp. Taking into account that the lamps were put out early, they were virtually paying at the rate of £60 or £70 a lamp, as compared with the other system, under which the lamps were kept burning all night.—At a meeting of the Eastbourne Town Council it was reported by the Lighting and General Purposes Committee that on August 23rd a letter was read from the secretary to the Eastbourne Electric Light Company, stating that the directors had considered the offer of the Corporation, and come to the conclusion that they cannot supply the parade arc lamps at less than £35 per lamp per annum. It was, therefore, resolved: "That this committee cannot see their way to recommend the council to renew the contract for lighting the parades by the electric light at the rate of £35 per lamp per annum, at the expiration of the present contract, the electric light company having definitely refused the compromise promised by the council."

Richmond.—At the recent half-yearly meeting of the Richmond Gas Company, the chairman, in moving the adoption of the report and balance-sheet, commented upon several items, and then went on to remark that he did not

Digitized by Google

think they needed to alarm themselves about a certain matter which had been suggested by the very loud voice of the press—namely, that they would have to look forward to the introduction of electric light into the town. During the past eighteen months they had made a reduction in the price of gas to the amount of 8d. per 1,000 cubic feet. This meant that their total annual charge for gas was about £4,800 less than before. If they could show that they were able to supply gas at 2s. 10d. per 1,000 cubic feet, as they were now doing, he did not think they needed to fear anything with regard to electric light. They had yet to learn that the electric light would be a success. It had not hitherto been so in any place that he knew of. The *Richmond and Kingston Express*, in commenting upon this attitude of the gas company, says: "The chairman of the Richmond Gas Company, at the half-yearly meeting, made the remark that he had yet to learn that the electric light was a success, and that he did not think they need alarm themselves about it. The latter point—that of alarm—he is quite right in, providing only he is ready to march with the times, for gas is constantly extending its usefulness. Gas is not likely to be doomed. But in the manner of obviating this danger he is at sea. Electric light is certainly now in such a position, that to say it is 'nowhere a success' is simply shutting one's eyes to facts. In nearly every country other than England (where a restrictive Act has been till lately in force) towns, and even little villages, in great number have adopted the light and with a successful competition with gas. It is a fact to be borne in mind by the worthy chairman that sweetness and purity, cleanliness and beauty are also paid for in obtaining his rival the electric light, and people, once having tried it, have been known to say that they would willingly pay three or four times the price for the better quality, were that the difference in price. There is this comfort, however, for the company, that they are already themselves in the field for supply of light, and if they are sharp sighted enough, could always keep the ground by undertaking the supply themselves. It is evident that money for maintenance and extension of plant necessary for renewal or maintenance of the gas plant, if applied instead to auxiliary electric lighting, would also bring in dividends if properly worked, and the ground would be kept by the company themselves. This attitude has, we understand, been taken by numerous gas companies in America and also in France; where, for instance, at Marseilles, the public lamps have two services, one of electric light till midnight, and till dawn a feebler single gas jet; the more wealthy customers are also being supplied. There is little doubt this example will be followed by many English gas companies, and Richmond may do the same. Any of the great electrical engineering firms—Crompton's of Chelmsford, the Brush Corporation, of Lambeth, Gulcher's, of Battersea, and others—will be found willing enough to afford free information, and to co-operate with the gas company in keeping their dividends. But if the gas company think they will keep the whole of the lighting still to gas merely by reducing their price, they will be as much mistaken as to expect everyone to drink beer simply because it it is cheaper than wine. *Verbum sap.*"

Electric Heaters.—The principle of electric heating, being based upon the reconversion of electricity, cannot be economical upon any considerable scale under the present conditions of generating electricity. Steam-engines only utilise 10 per cent. of the power of the coal burnt, and a dynamo will only utilise about 80 per cent. of this; so that about six times the amount of heat necessary would have to be generated to that of a stove utilising half the heat of the coal. Yet there are conditions under which electric heaters may be useful. The first is that in which electricity is generated by some agency inexpensive in fuel—such as wind, water, or the kinetic energy of some moving body (a train, for instance, running down hill) which has to be stopped. The other is when a large and economical system of electric distribution is at hand, and small quantities of heat are required, or for short periods of time. In such cases the actual (though still the uneconomical) expenditure of heat may be considerably less that the expenditure of preparing a fire, lighting it, using it, and letting it go out. For heating, then, where costless power is available, and for heating in temporary culinary and other operations, a future may exist for the electric heaters; and a field is also open for the heating of electric cars in winter where the current is already at hand. Dr. W. Leigh Burton, of Richmond, Virginia, has given many years' attention to the subject of electric heaters, having experienced innumerable discouragements and rebuffs, and has at last converted Prof. Houston and Mr. Van Depoele to his ideas of the usefulness of this invention. A general idea of the Burton electric heater may be had by stating that it consisted of an alternate arrangement of obstructing media and free conductors or radiators, arranged in a compact form, and insulated within a fire-proof casing, covered by a metal plate. In this heater the "obstructing media" consisted of platinum wire No. 25, and the "free conductors" of copper blocks one inch and three-quarters long, and half an inch square. The electrical resistance of the first type was low compared with the heater in its present form, owing to the fact that the aggregate length of the obstructing media in the entire coil would only amount to a little over one foot of platinum wire of the size indicated. In May, 1882, the first test was made with the heater with a current from a dynamo machine at Richmond, and here it was demonstrated that the heater "had a future." The copper blocks of the resistance coil were heated to redness by the heat developed in the platinum wire, the dynamo being driven at one-third speed. At another test water was boiled and meat cooked; and taking advantage of the boiling water to cook eggs, these were eaten at the table of the inventor the same evening. A further test of a heater by a dynamo current was made in the spring of 1884, when a ten-light Thomson-Houston dynamo was used, and the heater, having only one-tenth of an ohm resistance, was placed in circuit with the lamps, being probably the first instance in which heat and light were produced from the same current of electricity. Mr. Van Depoele has also had heaters connected on an arc lamp circuit. The proposition of the inventor was to use electric heaters on the railway trains where the use of coke or petroleum stoves has been fraught with such dire results. The power was to be obtained from a dynamo geared to the axle of the cars. The modern instrument consists essentially of a box of sheet iron, strung with resistance wires, and the whole covered with powdered fireclay and securely closed in. Tests made by Lieut. S. Dana Greene showed "that it was possible to warm a car or a room with electricity with a use of current representing in mechanical energy three-fourths of one h.p." The cars of the Richmond Union Electric Railway will be equipped with these heaters, and it would seem that the feasibility of the invention has been established beyond question.

THE MAGNETIC FIELD.—III.

All the mechanical phenomena here described are illustrations of electro-magnetic phenomena which can be produced by the apparatus shown in Fig. 3. Let S S be a straight wire threaded through an iron ring, B. The ring is not absolutely necessary, as a field is produced also in the air surrounding the wire, but to make the analogy with the box containing water more striking, it is better to represent the field in a somewhat similar form—viz., as contained in a cylindrical iron ring of definite dimensions. Let the ends of the wire be connected with a battery, E, and let there be a key, A, by which the circuit can be closed and opened. The closing of the key corresponds to the putting of the weight on the pan on the right-hand side of Fig. 2, and the opening corresponds to the removal of the weight. The E.M.F. of the battery represents the pull exerted by the weight, and the electrical resistance of the circuit takes the place of the friction of the pulley. Upon closing the key A a current will commence to flow from the positive pole of the battery up to the straight wire, and through the ring from left to right, returning down on the other side to the negative pole of the battery. Just as in the mechanical model the speed of advance of the shaft was gradually increased from zero to its final maximum value, so will now the strength of this current gradually grow until the final value, as defined by Ohm's law, has been attained. This final value does in no way

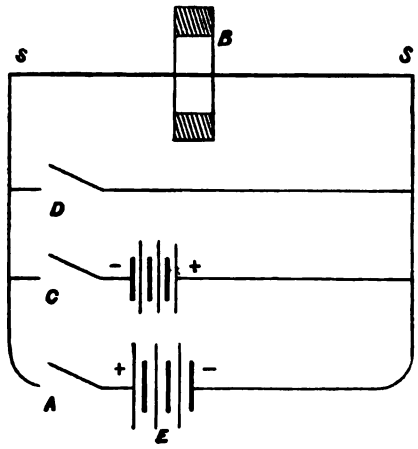

FIG. 3

depend upon the dimensions of the iron ring, B, but is simply the ratio of E.M.F. and resistance. Now let us simultaneously open the key A, and close the key D. This would correspond to the removal of the cord on the right of Fig. 1, and the placing of it on the left, but without the weight. The current will now continue flowing round the circuit S S D in the direction of the hands of a watch, but with gradually diminishing strength, just as in the mechanical model the motion of the shaft was gradually arrested by the friction of the pulley. Now open D, and start the original current again by closing A. When the current has become steady, open A and close C simultaneously. In the circuit of this key we suppose to be inserted a second battery, which tends to produce a current in the wire, S S, in the opposite direction to that of the first battery. The closing of the key C then corresponds to our placing the weight into the pan to the left of Fig. 2, as shown by dotted lines. Just as in the previous case the weight was raised by the inertia of the moving water so storing mechanical energy, so will now electrical energy be stored in the second battery. Suppose this to be a Planté cell, then we would be able at any future time to call forth this energy for working a motor or doing any other kind of work, just as we could utilise the energy of position contained in the raised weight for driving some piece of machinery by allowing the weight to descend again to its original level. We have now, at least for two experiments, shown that there is perfect analogy between the electrical apparatus and the mechanical model we have devised for representing it. There remains yet another experiment—namely, that of rupturing the cord. The rupture was produced by unduly increasing the friction of the pulley. Now, as friction in our model represents the electrical resistance of the circuit in the real apparatus, we have only to unduly increase this resistance in order to produce an effect which corresponds to the breaking of the cord. This can easily be done by simply opening the key A, without closing any of the other keys. By opening this key we increase the resistance of the circuit very nearly to infinity, and the result is a spark, or violent discharge of electricity and rupture of the air between the severed points of the circuit. It will be seen the analogy is perfect also in this respect.

We have in the foregoing only represented the phenomena in a general way without inquiring whether the apparatus was an efficient one. Let us now consider this matter somewhat more in detail. Say the machine represented in Fig. 2 is required for storing potential energy (energy of position as represented by the raised weight, W), how should the details be arranged in order that this object may be attained with the least possible relative loss of energy? The answer is obvious. We must reduce the friction of the pulleys as much as possible, and increase the quantity and velocity of the water in the box; in other words, we must make the box large and the pitch

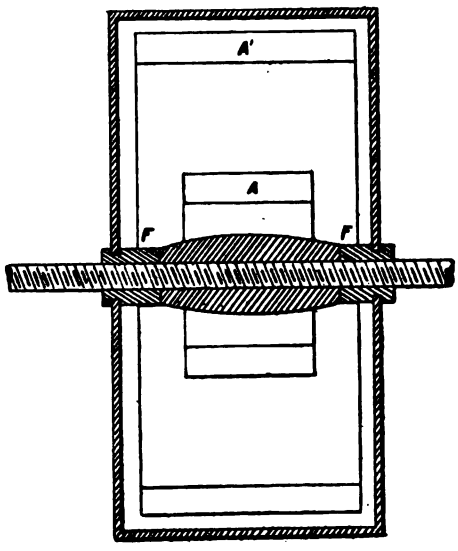

FIG. 4.

of the screw small. By this means we shall reduce the linear velocity of the shaft, and with it the energy lost in friction, whilst at the same time we increase the energy flowing through the whole system, thus raising the coefficient of efficiency. A similar result will also follow from an increase of the weights, for it must be remembered that according to our original assumption the friction depends only on the speed, but not on the pull in the cords. Reasoning from analogy, we can now at once determine the conditions which will make the electrical apparatus efficient. These are in the order corresponding to the above. A low electrical resistance of the circuit, a large mass of iron surrounding the wire, threading the wire many times through the iron ring, and a high E.M.F. of the two batteries. All these conditions, with the exception of the third, are self-evident from analogy; the third, corresponding to the employment of a screw of small pitch, requires some explanation. Now the effect of such a screw is that to a small linear advance of the shaft corresponds a large rotative velocity of the water, or, translated into electrical language, to a small current corresponds a strong magnetic field. We may imagine a strong current to be composed of a number of weak currents flowing side by side. Such a current will produce a strong field, and this result can therefore be obtained by threading the wire, S S, many times through the iron ring; in fact, by making a coil of it.

The foregoing and somewhat lengthy explanation will have shown the reader that our mechanical model can be used to represent a good many electro-magnetic phenomena,

Digitized by Google

but still it is not perfect, for it fails to represent one very important phenomenon. We allude to the fact that although a current will always produce a field, a permanent—that is, an unchanging field—does not produce or maintain a current in a wire within the influence of that field. In this respect the model represented in Fig. 2 is at fault, for if by some means we keep the water rotating in the box, there will be a constant tendency to push the screw forward. According to this model, therefore, a permanent field should create an E.M.F. in a wire at rest within the influence of the field, which is contrary to experience. We must consequently alter our model to make it correctly represent this important experimental fact. Fig. 4 shows this new arrangement. It differs from the previous arrangement by the way the feather, F, is fixed. In Fig. 2, the piece to which the feather is attached is a fixture, but in Fig. 4 we replace the fixed support by connections with a second set of paddles, A', contained in the same box as the paddles, A, but set much farther from the centre. As long as the water in the box is quiescent, the paddles, A, will prevent the shaft from rotating almost as completely as if the pieces, F, which carry the feathers engaging into the keyway of the shaft, were fixtures in space, and as we suppose the distance between the two sets of paddles to be considerable, it will be necessary for the inner wheel to revolve some time before motion is communicated to the outer layers of water, and during that time the action of this model will be very similar to that of the model represented by Fig. 2. But let us assume that the whole body of water in the box has been set into uniform rotation by some external means. The two sets of paddles will then revolve with the same angular velocity—that is to say, the screw and its nut will be turned at the same rate, and consequently there will be no advance of the shaft. Our model now illustrates the case of a wire passing through a permanent—that is, unchanging—field, itself remaining at rest, when, as is well known, the field does not produce a current in the wire; just as the whirl of the water within the box does not produce longitudinal motion of the screw shaft.

Now let us see what happens if we accelerate the motion of the water; the outer paddles will be influenced sooner than the inner ones, and overtake them. As we need only consider the relative motion of the two sets of paddles, we may assume the outer paddles to stand still and the inner paddles to turn backwards. To fix ideas, we suppose the motion of the water to be from the observer on the top and towards the observer at the bottom, a direction of the field which in Fig. 2 is produced by moving the shaft to the right. The motion now impressed upon the shaft will therefore be the same as if we prevented it from revolving whilst turning the paddle-wheel, A, in the opposite direction to that in which the water flows. The shaft will now advance to the left. We thus find that an increase in the strength of the field tends to produce a current of opposite direction to that which, acting alone, would produce the same field. Similarly, if we retard the flow of water, the inner paddles will overtake the outer ones, and cause the shaft to advance to the right. Electromagnetically expressed, a diminution of the strength of the field tends to produce a current in such a direction as tends to preserve the original field. These results could also have been deduced from the model shown in Fig. 2, for upon increasing the linear speed of the shaft by applying a heavier weight in the right-hand pan, the screw experiences a resistance equivalent to a thrust to the left corresponding to an E.M.F. acting from right to left, and by removing some of the weight the water would overtake the paddles, and produce an additional thrust on the screw equivalent to an E.M.F. acting from left to right. In either case the change in the strength of the field produced by a change in the current reacts upon the current in such a way as tends to bring it back to its original condition. This fundamental principle is known under the name of its discoverer as Lenz's law. We might, however, have deduced this law, without any reference to our models, simply from the universal principle of the conservation of energy. For if an increase of current were not accompanied by the creation of a counter E.M.F., the additional energy represented by the stronger field could be obtained without a proportional expenditure of energy in some other form, which would be nothing more or less than perpetual motion. Having illustrated the nature of the magnetic field as far as this is possible by mechanical models, which must necessarily always be somewhat crude, we can now proceed to treat the subject in a more rigourously scientific manner without in all cases attempting mechanical illustrations; and we begin by the investigation of the influence of a straight current upon a free magnet pole.

It has already been pointed out that the stream-lines surrounding the wire in a kind of magnetic whirl, tend to propel a free pole in the direction of their flow. As, however, a free magnet-pole is a physical impossibility, there being always two poles of opposite sign in a magnet, this tendency shows itself in a rotation of the magnet, so as to bring its length into a right-angle position to the wire. We imagine the magnet to be the vehicle, or carrier, of its own field, the stream-lines issuing at the north pole, passing through the air, and entering the metal again at the south pole. Let, in Fig. 5, W be the section of the wire carrying a current downwards or from the observer, which we indicate by placing a dot into the circle representing the wire, an upward current being indicated by a small cross—thus, × —and let S be one of the stream-lines belonging to the field of the wire. Let N, C, D, S and N, A, B, S be two of the stream-lines belonging to the field of the magnet, then, from what has been already explained, it will be clear that there will be attraction between the lines S and N, C, and repulsion between the lines S and N, A. These forces produce a couple tending to turn the magnet round O, as a fixed centre, in a counter clockwise direction.

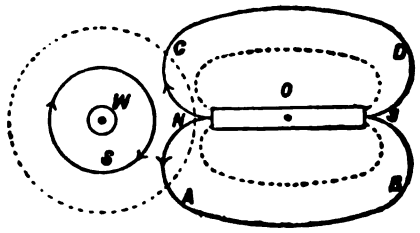

FIG. 5.

Similarly, all the stream-lines, S, which lie to the left of the stream-lines N, C, and N, A, must produce the same result, whilst all the stream-lines of the magnet to the right of S will also tend to turn the latter in a counter clockwise direction. Those stream-lines of wire and magnet which cut each other will tend to produce the opposite effect, but as their density decreases with an increase of distance from the pole and from the wire, the differential effect of all the lines will still be in the sense of producing a counter clockwise rotation of the magnet. This theory is confirmed by actual experiment. The magnet, if free to follow the influence of the field of the wire, sets itself so that its axis forms a tangent to a circle drawn round the wire as centre. Expressed in other words, the current produces on the pole a force at right angles to the plane laid through the wire conveying the current and the pole.

THE BRITISH ASSOCIATION.

ADDRESS TO THE MECHANICAL SCIENCE SECTION BY WILLIAM HENRY PREECE, F.R.S., M.I.C.E., ETC., PRESIDENT OF THE SECTION.

"Canst thou send lightnings, that they may go and say unto thee, Here we are?" were pregnant words addressed to Job unknown centuries ago. They express the first recorded idea in history of the potentiality of electricity to minister to the wants of mankind. From Job to Franklin is a long swing in the pendulum of time. It was not until that American philosopher brought down atmospheric electricity by his kite-string in 1747, and showed that we could lead it where we willed, that we were able to answer the question addressed to the ancient patriarch. Nearly another century elapsed before this mysterious power of Nature was fairly conquered. It has been during this generation, and during the life of the British Association,

Digitized by Google

that electricity has been usefully employed; and it is because I have taken a subordinate position in inaugurating nearly all of its practical applications, that I venture to make the developments of them the text of my address to this section.

People are singularly callous in matters affecting their own personal safety; they will not believe in mysteries, and they ridicule or condemn that which they do not understand. The Church itself set its face against Franklin's "impious" theories, and he was laughed to scorn by Europe's scientific sons; and even now, though commissions composed of the ablest men of the land have sat and reported on Franklin's work in England, France, and nearly every civilised nation, the public generally remains not only ignorant of the use of lightning conductors, but absolutely indifferent to their erection, and, if erected, certainly careless of their proper maintenance. I found in a church not very far from here the conductor leaded into a tombstone, and in a neighbouring cathedral the conductor only a few inches in the ground, so that I could draw it out with my hand. Although I called the attention of the proper authorities to the absolute danger of the state of affairs, they remained in the same condition for years.

Wren's beautiful steeple in Fleet-street (St. Bride's) was well-nigh destroyed by lightning in 1764. A lightning rod was fixed, but so imperfectly that it was again struck. In July last (1887) it was damaged because the conductor had been neglected, and had lost its efficiency.

As long as points remain points, as long as conductors remain conductors, as long as the rods make proper connection with the earth, lightning protectors will protect; but if points are allowed to be fused or to corrode away, as long as bad joints or faulty connections are allowed to remain, as long as bad earths or no earths exist, so long will protectors cease to protect, and they will become absolute sources of danger. Lightning conductors, if properly erected, duly maintained, and periodically inspected, are an absolute source of safety; but if erected by the village blacksmith, maintained by the economical churchwarden, and never inspected at all, a loud report will some day be heard, and the beautiful steeple will convert the churchyard into a new geological formation.

We have not yet acquired that mental confidence in the accuracy of the laws that guide our procedure in protecting buildings from the effects of atmospheric electrical discharges which characterises most of the practical applications of electricity. Some of our cherished principles have only very recently received a rough shaking from the lips of Prof. Oliver Lodge, F.R.S., who, however, has supported his brilliant experiments by rather fanciful speculation, and whose revolutionary conclusions are scarcely the logical deduction from his novel premisses. The whole subject is going to be thoroughly discussed at this meeting.

We are now obtaining much valuable information about the nature of lightning from photography. We learn that it does not, as a rule, take that zigzag course conventionally used to represent a flash on canvas. Its course is much more erratic and sinuous, its construction more complicated, and pictures have been obtained of *dark* flashes whose *raison d'être* has not yet been satisfactorily accounted for. The network of telegraph wires all over the country is peculiarly subject to the effects of atmospheric electricity, but we have completely mastered the vagaries of lightning discharge in our apparatus and cables. Accidents are now very few and far between.

The art of transmitting intelligence to a distance beyond the reach of the ear and the eye, by the instantaneous effects of electricity, had been the dream of the philosopher for nearly a century, when, in 1837, it was rendered a practical success by the commercial and far-sighted energy of Cooke, and the scientific knowledge and inventive genius of Wheatstone. The metallic arc of Galvani (1790) and the developments of Volta (1796) had been so far improved that currents could be generated of any strength, the law of Ohm (1828) had shown how they could be transmitted to any distances, the deflection of the magnetic needle by Oersted in 1819, and the formation of an electro-magnet by Ampère and Sturgeon, and the attraction of its armature had indicated how those currents could be rendered visible as well as audible.

Cooke and Wheatstone in 1837 utilised the deflection of the needle to the right and to the left to form an alphabet. Morse used the attraction of the armature of an electro-magnet to raise a metal style to impress or emboss moving paper with visible dots and dashes. Steinheil imprinted dots in ink on the different sides of a line on paper, and also struck two bells of different sound to affect the ear. Bréguet reproduced in miniature the actual movements of the semaphore then so much in use in France; while others rendered practical the favourite idea of moving an indicator around a dial, on which the alphabet and the numerals were printed, and causing it to dwell against the symbol to be read—the A, B, C instrument of Wheatstone in England and of Siemens in Germany. Wheatstone conceived the notion of printing the actual letters of the alphabet in bold Roman type on paper—a plan which was made a perfect success by Hughes in 1854.

At the present moment the needle system of Cooke and Wheatstone, as well as the A, B, C dial telegraph, are very largely used in England on our railways and in our smaller post-offices. The Morse recorder and the Hughes type-printer are universally used on the Continent; while in America the dot and dash alphabet of Morse is impressed on the consciousness through the ear by the sound of the moving armature striking against the stops that limits its motion. In our larger and busier offices the Morse sounder and the bell system, as perfected by Bright, are very largely used, while the Press of this country is supplied with news which is recorded on paper by ink dots and dashes at a speed that is almost fabulous.

Sir William Thomson's mirror—the most delicate form of the needle system—where the vibratory motions of an imponderable ray of light convey words to the reader, and his recorder, where the wavy motion of a line of ink spirted on paper by the frictionless repulsion of electricity performs the same function, are exclusively employed on our long submarine cables.

Bakewell, in 1848, showed how it was possible to reproduce facsimiles of handwriting and of drawing at a distance, and in 1879 E. A. Cowper reproduced one's own handwriting, the moving pen at one station so controlling the currents flowing on the line wire that they caused a similar pen to make similar motions at the other distant station. Neither of these plans, the former beautifully developed by Caselli and d'Arlincourt, and the latter improved by Robertson and Elisha Gray, have yet reached the practical stage.

The perfection of telegraphy has been attained by that chief marvel of this electrical age—the speaking telephone of Graham Bell. The reproduction of the human voice at a distance, restricted only by geographical limits, seems to have reached the confines of human ingenuity; and though wild enthusiasts have dreamt of reproducing objects abroad visible to the naked eye at home, no one at the present moment can say that such a thing is possible, while in the face of the wonders that have been done no one dare say that it is impossible.

The commercial business of telegraphy, when our thoughts and wishes, orders and wants, could be transmitted for money, was inaugurated in this country by the establishment of the Electric Telegraph Company in 1846, and until 1870 it remained in the hands of private enterprise, when it was purchased by the Government, and placed under the sole control of the Postmaster-General. It has been the fashion to decry the terms of purchase of the various undertakings then at work by those who have not understood the question, and by those who, being politically opposed to the Government in power at the time, saw all their acts, not only through a glass darkly, but through a reversing lens. A business producing £550,000 per annum was bought at twenty years' purchase, and that business has now increased to £2,000,000 per annum. Six million messages per annum have increased to 52,000,000.

Every post office has been made a telegraph office, every village of any size has its wire; messages which used to cost 12s. 6d. are now sent for 6d.; a tariff which was vexatious from its unfair variation is now uniform over the United Kingdom, and no one can justly complain of error or delay in the transmission of their messages. Silly complaints are sometimes inserted in the press of errors which the most elementary knowledge of the Morse alphabet would detect, and little credit is given to the fact that the most perfect

Digitized by Google

telegraph is subject to strange disturbances from terrestrial and atmospheric causes which admit sources of error beyond the control of the telegraphist. A flash of lightning in America may cause an extra dot in Europe, and *man* may become *war*. An earthquake in Japan may send a dash through France, and *life* would become *wife*. A wild goose flying against a telegraph wire might drive it into momentary contact with another wire, and *sight* might become *night*. Everyone should know his Morse alphabet, and people should learn how to write—nine-tenths of the errors made are due to the execrable caligraphy of the present day. As a matter of fact, in ninety-nine cases out of a hundred, the telegraphist delivers to the editor of a newspaper "copy" far more accurate than the first proof of his own leader submitted by the printer. The quantity of news transmitted is enormous, an average of 1,538,270 words are delivered per day. The recent convention in Chicago, when the Republican party of the United States nominated their candidate for the presidentship, created so much business that every American paper has chronicled this big thing as unique; 500,000 words were sent on one night, but we in England, when Mr. Gladstone introduced his celebrated Home Rule Bill on April 8, 1886, sent from the Central Telegraph Office in London 1,500,000 words.

The growth of business has led to vast improvement in the carrying capacity of the wires. Cooke and Wheatstone required five wires for the first needle instrument to work at the rate of four words per minute. One wire can now convey six messages at ten times the speed. The first Morse apparatus could work at about five words a minute; we now transmit news at the rate of 600 words a minute. In 1875 it was thought wonderful to transmit messages to Ireland at 80 words a minute. When I was recently at Belfast I timed messages coming at the rate of 461 words a minute. Duplex working—that is, two messages travelling on the same wire at the same time in opposite directions, the invention of Gintl, of Vienna—is now the normal mode of working; Edison's quadruplex is common; and the Delany system of multiplex working is gradually being introduced, by which six messages are indiscriminately sent in either direction. The telegraphic system of England has been brought to the highest pitch of perfection. We have neither neglected the inventions of other countries, nor have we been chary of exercising inventive skill ourselves, and we have received our full meed of that reward which is always freely bestowed on a British Government official, neglect and abuse. All parts of the civilised world are now united by submarine cables. The *Times* every morning has despatches from every quarter of the globe, giving the news of the previous day; 110,000 miles of cable have been laid by British ships, and nearly £40,000,000 of British capital has been expended by private enterprise in completing this grand undertaking. A fleet of 37 ships is maintained in various oceans to lay new cables and to repair breaks and faults as they occur—faults that arise, among other causes, from chafing on coral reefs, ships' anchors, the onslaught of insects, and earthquakes. The two cables connecting Australia and Java were recently simultaneously broken by an earthquake.

The politician, unmindful of the works of the engineer, is apt to apply to the credit of his own proceedings the growing prosperity of the world. The engineer, however, feels that steam and electricity in his hands have done more to economise labour, to cheapen life, to increase wealth, to promote international friendship, to alleviate suffering, to ward off war, to encourage peace, than all the legislation and all the verbosity of the politician.

The railways of this country are entirely dependent for the conduct of their traffic on the telegraph, and the security of their passengers is mainly due to the working of the block system. A railway, say, between London and Bath, is broken up into certain short sections, and only one train is allowed on one section at one time. The presence, motion, and departure of trains is announced and controlled by electric signals, and the out-door signals are governed by these electric signals. There are few more interesting places to visit than a well-equipped signal-box on one of our main railways. The signalman is able to survey the lines all around and about him by aid of his electric signals. He can talk by telegraph or by telephone to his neighbours and his station-master; he learns of the motion of the trains he is marshalling by the different sounds of electric bells; he controls his out-door signals by the deflection of needles or the movement of miniature semaphores; he learns the true working of his distant signals by their electrical repetition; machinery governs and locks every motion he makes so that he cannot make a mistake. The safety of railway travelling is indicated by the fact that while in the five years ending 1878 thirty-five people were killed annually from causes beyond their own control, in the five years ending 1887 the average has been reduced to sixteen. One person is killed in 35,000,000 journeys made by train. Wherever we are dependent on human agency we are subject to human error, and a serious accident very recently at Hampton has shown how the most perfect machinery may be rendered valueless to protect life when perversity, thoughtlessness, or criminality enter as factors into the case.

At the meeting of the Association in Plymouth in 1877 I was able for the first time in this country to show the telephone at work. Since then its use has advanced with giant strides. There are probably a million instruments at work now throughout the civilised world. Its development has been regularly chronicled at our meetings. As far as the receiving part of the apparatus is concerned, it remains precisely the same as that which I brought over from America in 1877; but the transmitter, ever since the discovery of the microphone by Hughes in 1878, has been entirely remodelled. Edison's carbon transmitter was a great step in advance; but the modern transmitters of Moseley, Berliner, D'Arsonval, De Jongh, leave little to be desired. The disturbances due to induction have been entirely eliminated, and the laws regulating the distance to which speech is possible are so well known, that the specification of the circuit required to connect the Land's End with John O'Groat's by telephone is a simple question of calculation. A circuit has been erected between Paris and Marseilles, 600 miles apart, with two copper wires of 6½ gauge, weighing 540lb. per mile, and conversation is easily maintained between those important cities at the cost of three francs for three minutes. One scarcely knows which fact is the more astounding—the distance at which the human voice can be reproduced, or the ridiculously simple apparatus that performs the reproduction. But more marvellous than either is the extreme sensitiveness of the instrument itself, for the energy contained in one heat unit (gramme-water-degree) would, according to Pellat, maintain a continuous sound for 10,000 years.

The influence which electric currents exert on neighbouring wire extends to enormous distances, and communication between trains, and ships in motion, between armies inside and outside besieged cities, between islands and the mainland, has become possible without the aid of wires at all, by the induction which is exerted through space itself. On the Lehigh Valley Railway, in the United States, such a system of telegraphing without wires is in actual daily use.

The conduct of telephonic business in England is still in the hands of those who hold the patents, and who maintain a most rigid monopoly. These patents have only a short period to run, and when they expire we may expect to find that England will not occupy the very retired position she holds now as a telephone country. Stockholm has more subscribers than London; there are 15,000 subscribers in and about New York, while the number in London is only 4,851.

Electric lighting has become popular, not alone from the beauty of the light itself, but from its great hygienic qualities in maintaining the purity and coolness of the air we breathe. The electric light need not be more brilliant than gas; but it must be more healthy. It need not be cooler than a wax candle; but it must be brighter, steadier, and more pleasant to the eye. In fact, it can be rendered the most perfect artificial illuminant at our disposal, for it can illumine a room without being seen directly by the eye; it can be made absolutely steady and uniform without irritating the retina; it does not poison the air by carbonic acid and carbonic oxide, or dirty the decorations by depositing unconsumed carbon; it does not destroy books or articles of vertu and art by forming water which absorbs sulphur acids; and it does not unnecessarily heat the room.

Other Places.....	4s. 10d. ...	9s. 8d. ...	19s 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, ESQ., *President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of* W. H. WOLLASTON, M.D., F.R.S., *and on April 20th we gave that of* SIR HUMPHRY DAVY, F.R.S., *whose fame as an electrician is still more prominent than that of* WOLLASTON. *Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of* PROF. D. E. HUGHES, F.R.S.

THE PRESIDENTIAL ADDRESS.

It is customary for the majority of technical papers to report almost, or quite verbatim, the presidential address as delivered each succeeding year at the meeting of the British Association, and, for the matter of that, most of the ordinary political papers go and do likewise. With all due deference to the transcendental scientific attainments of the various presidents, it may be taken as almost capable of proof that these addresses are printed because it is the fashion so to do, and not because the responsible authorities believe for a moment they are valuable. It has been our lot to try to hear and attempt to read many of these lucubrations, but the former has generally ended in failure and the latter in despair. Only a moderate number can comfortably hear the sound of the human voice, and when twice that number attempt to do so one half usually and naturally fail in their endeavour. With regard to reading through a long address, life is too short. The average man, who must be able to throw in a remark during a casual conversation, depends upon similar casual remarks he may hear, or upon the trebly concentrated essence of the address given by some newspaper. Catch phrases soon obtain a footing, and these satisfy the ordinary man, and especially the supporters of the association whose *ultima Thule* is the number of garden parties, conversaziones, and excursions that can be crammed into the week's athletics. We follow the fashion and go with the stream simply because it is easier to pull with the tide than against it. But though we believe that Sir Frederick Bramwell's address will go the way of all such addresses, it has certain conspicuous peculiarities that must remove it from the realms of commonplace. In the first place, if one may contradict ourselves, to venture upon an Irishism, it is commonplace—commonplace enough to be understanded of the multitude. It is an *olla podrida*, each constituent of which directly appeals to a different class. It sets no one's back up, except maybe in the reference to the Channel tunnel. Simple truths are too often forgotten in the endeavour to pose before an expectant world as the exponent of some recondite scientific speculation, which is understood by not half-a-dozen beings in the universe, and which raises the criticisms of wonder at the "creature's knowledge," which really is another way of condoning our own ignorance or cowardice to make believe that we understand things utterly beyond our comprehension. "What in the name of goodness is he driving at"? is a question which frequently flashes through the minds of those who listen to papers and discussions, but finds no voice because the thinker is fearful of showing his ignorance.

To return, however, to Sir Frederick Bramwell's address, the text of which is "Next-to-nothing"; the same may be said of this article—sketchy, discursive,

Digitized by Google

rambling, inane, are the adjectives applied, yet no one denies the correctness of what is said. Perhaps the sentences most pregnant with food for thought are those referring to Watt. It is said: "To Watt, also, we owe that great source of economic working, the knowledge of the expansive force of steam; and to his prescience we owe the steam jacket, without which expansion, beyond certain limits, is practically worthless. I have said 'prescience'—foreknowledge—but I feel inclined to say that, in this case, prescience may be rendered 'pre-science,' for I think that Watt felt the utility of the steam jacket, without being able to say on what ground that utility was based." It is the opinion of a great many people that the so-called scientific men—the writers of papers of the intellectual gymnastic kind, the wielders of pepper boxes filled with algebraic symbols—are a little too arrogant in their tones when they endeavour to maintain that they are the salt of the earth, and that, without them, progress would stand still "like Joshua's moon in Ajalon." Men not filled to the brim with this kind of science sometimes *feel* that something is wanted, and straightway proceed to invent that something. The major portion of inventors whose works are of a practical character have little knowledge of the higher flights of science, and are frequently very weak as regards the rudiments. They, however, show what can be done, and subsequently the mathematicians demonstrate it can be done, and why it can be done. Greater credit is due to those who feel rather than know, even though they may not be Watts. Of our own particular branch of science and its applications the President does not say much, though he may think the more, for what reference there is comes in the forefront of the address. It is quite true there is "no branch of science towards which the public looks with greater hope of practical benefits" than to electricity, and when we contemplate the progress that has been made in this direction since the last meeting of the Association at Bath seventy-four years ago, it cannot be denied that such looking is justified and justifiable. In '64 the telephone and microphone, electric light and electric traction were things to come, now they are realities; the speed of telegraphing then was tame in comparison with what it is now; submarine telegraphy practically was not—its failures had been many, but now, like Crusoe's lordship, from this island as centre to the uttermost parts of the earth its ramifications may be traced, its success has been constant, its value to humanity incalculable.

There is no reason to suppose that the rate of progress will diminish, and it may be found that electricity is destined to play no inconsiderable part in the realisation of the President's prophecy that at the centenary of the Association in 1931 steam will have been relegated to the museums. It is not that in its present applications electricity provides a prime motor, but that, notwithstanding Lord Rayleigh's demonstration to the contrary, men's minds are tending towards the direct conversion of heat into electricity. That this is economically impossible remains to be proved, and it remains a subject for the discussion of future generations of members of the British Association.

CORRESPONDENCE.

FLATS ON THE COMMUTATOR.

TO THE EDITOR OF THE ELECTRICAL ENGINEER.

SIR,—In your last week's selection of "Leaves from the Diary of a Young Electrician," I observe that the author attributes "flats" on the commutator to softness of the segments on which the flat occurs.

I have found that almost invariably this is due to a defective connection of those segments to the armature, producing, by the resistance it introduces, a greater difference of potential across that particular section than its proper share of the total; the remedy being resoldering of the connections. Of course, when the flat has once begun, the jumping of the brushes aggravates the evil, but bad connection will usually be found to be the primary cause.—Yours, &c.,

T. M. WINSTANLEY WALLIS.

Derby, September 3, 1888.

THE BRITISH ASSOCIATION AT BATH.

The 58th annual meeting of the British Association was opened on Wednesday at Bath. The retiring president, Sir Henry Roscoe, after alluding to the previous meeting at Bath, in 1864, which was presided over by Sir Chas. Lyell, "of beloved and venerated memory," representing the domains of pure science, introduced Sir Frederick Bramwell as the exponent of applied science. Sir F. Bramwell then took the chair amid loud cheers, and delivered the following address:

PRESIDENTIAL ADDRESS BY SIR FREDERICK BRAMWELL, D.C.L., F.R.S., M.I.C.E.

The late Lord Iddesleigh delighted an audience for a whole evening by an address on "Nothing." Would that I had his talents, and could discourse to you as charmingly as he did to his audience, but I dare not try to talk about "Nothing." I do, however, propose, as one of the two sections of my address, to discourse to you on the importance of the "Next-to-Nothing.' The other section is far removed from this microscopic quantity, as it will embrace the "Eulogy of the Civil Engineer," and will point out the value to science of his works.

I do not intend to follow any system in dealing with these two sections. I shall not even do as Mr. Dick, in "David Copperfield" did—have two papers, to one of which it was suggested he should confine his Memorial and his observations as to King Charles's head. The result is, you will find, that the importance of the next-to-nothing, and the laudation of the civil engineer, will be mixed up in the most illogical and haphazard way throughout my address. I will leave to such of you as are of orderly minds the task of rearranging the subjects as you see fit, but I trust—arrangement or no arrangement—that by the time I have brought my address to a conclusion, I shall have convinced you that there is no man who more thoroughly appreciates the high importance of the "next-to-nothing" than the civil engineer of the present day, the object of my eulogy this evening.

If I may be allowed to express the scheme of this address in modern musical language, I will say that the "next-to-nothing" "motive" will commonly usher in the "praise-song" of the civil engineer; and it seems to me will do this very fitly, for in many cases it is by the patient and discriminating attention paid to the effect of the "next-to-nothing" that the civil engineer of the present day has achieved some of the labours of which I now wish to speak to you.

An association for the advancement of science is necessarily one of such broad scope in its objects, and is so thoroughly catholic as regards science, that the only possible way in which

Digitized by Google

it can carry out those objects at all is to segregate its members into various subsidiary bodies, or sections, engaged on particular branches of science. Even when this division is resorted to, it is a hardy thing to say that every conceivable scientific subject can be dealt with by the eight sections of the British Association. Nevertheless, as we know, for fifty-seven years the Association has carried on its labours under sections, and has earned the right to say that it has done good service to all branches of science.

Composed, as the Association is, of a union of separate sections, it is only right and according to the fitness of things that, as time goes on, your presidents should be selected, in some sort of rotation, from the various sections. This year it was felt by the council and the members that the time had once more arrived when Section G—the mechanical section—might put forward its claim to be represented in the presidency; the last time on which a purely engineering member filled the chair having been at Bristol in 1875, when that position was occupied by Sir John Hawkshaw. It is true that at Southampton, in 1882, our lamented friend, Sir William Siemens, was president, and it is also true that he was a most thorough engineer and representative of Section G; but all who knew his great scientific attainments will probably agree that, on that occasion, it was rather the Physical Section A which was represented, than the Mechanical Section G.

I am aware, it is said, Section G does not contribute much to pure science by original research, but that it devotes itself more to the application of science. There may be some foundation for this assertion, but I cannot refrain from the observation, that when engineers, such as Siemens, Rankine, Sir William Thomson, Fairbairn, or Armstrong make a scientific discovery, Section A says it is made, not in the capacity of an engineer, and therefore does not appertain to Section G, but in the capacity of a physicist, and therefore appertains to Section A—an illustration of the danger of a man's filling two positions, of which the composite prince-bishop is the well-known type. But I am not careful to labour this point, or even to dispute that Section G does not do much for *original* research. I don't agree it is a fact, but, for the purposes of this evening, I will concede it to be so. But what then? This Association is for the "advancement of science"—the *advancement*, be it remembered; and I wish to point out to you, and I trust I shall succeed in establishing, that for the *advancement* of science it is absolutely necessary there should be the *application* of science, and that, therefore, the section, which as much as any other (or, to state the fact more truly, which more than any other) in the Association *applies* science, is doing a very large share of the work of *advancing* science, and is fully entitled to be periodically represented in the presidency of the whole Association.

I trust also I shall prove to you that applications of science, and discoveries in pure science, act and re-act the one upon the other. I hope in this to carry the bulk of my audience with me, although there are some, I know, whose feelings, from a false notion of respect for science, would probably find vent in the "toast" which one has heard in another place—this "toast" being attributed to the pure scientist—"Here's to the latest scientific discovery: may it never do any good to anybody!"

To give an early illustration of this action and reaction, which I contend occurs, take the well-worn story of Galileo, Torricelli, and the pump-maker. It is recorded that Galileo first, and his pupil Torricelli afterwards, were led to investigate the question of atmospheric pressure by observing the failure of a pump to raise water by "suction" above a certain level. Perhaps you will say the pump-maker was not applying science, but was working without science. I answer, he was unknowingly applying it, and it was from that which arose in this unconscious application that the mind of the pure scientist was led to investigate the subject, and thereupon to discover the primary fact, of the pressure of the atmosphere, and the subsidiary facts which attend thereon. It may appear to many of you that the question of the exercise of pressure by the atmosphere should have been so very obvious, but little merit ought to have accrued to the discoverer; and that the statement, once made, must have been accepted almost as a mere truism. This was, however, by no means the case. Sir Kenelm Digby, in his "Treatise on the Nature of Bodies," printed in 1658, disputes the proposition altogether, and says, in effect, he is quite sure, the failure of the pump to raise water was due to imperfect workmanship of some kind or description, and had nothing to do with the pressure of the air, and there is no reason why a pump should not suck up water to any height. He cites the boy's sucker, which, when applied to a smooth stone, will lift it, and he says the reason why the stone follows the sucker is this. Each body must have some other body in contact with it. Now, the stone being in contact with the sucker, there is no reason why that contact should be broken up, for the mere purpose of substituting the contact of another body, such as the air. It seems pretty clear, therefore, that even to an acute and well-trained mind, such as that of Sir Kenelm Digby, it was by no means a truism, and to be forthwith accepted when once stated, that the rise of water on the "suction side" of a pump was due to atmospheric pressure. I hardly need point out that the pump-maker should have been a member of "G." Galileo and Torricelli, led to reflect by what they saw, should have been members of "A" of the then "Association for the Advancement of Science."

But passing away from the question of the value of the application of science of a date some two and a half centuries ago, let us come a little nearer to our own times.

Electricity—known in its simplest form to the Greeks by the results arising from the friction on amber, and named therefrom; afterwards produced from glass-cylinder machines, or from plate machines; and produced a century ago by the "Influence" machine—remained, as did the discoveries of Volta and Galvani, the pursuit of but a few, and even the brilliant experiments of Davy did not suffice to give very great impetus to this branch of physical science.

Ronalds, in 1823, constructed an electric telegraph. In 1837 the first commercial use was made of the telegraph, and from that time electrical science received an impulse such as it had never before experienced. Further scientific facts were discovered; fresh applications were made of these discoveries. These fresh applications led to renewed vigour in research, and there was the action and reaction of which I have spoken. In the year 1871 the Society of Telegraph-Engineers was established. In the year 1861 our own Association had appointed a committee to settle the question of electrical standards of resistance, which committee, with enlarged functions, continued its labours for twenty years, and of this committee I had the honour of being a member. The results of the labours of that committee endure (somewhat modified, it is true), and may be pointed to as one of the evidences of the value of the work done by the British Association. Since Ronald's time, how vast are the advances which have been made in electrical communication of intelligence by land lines, by submarine cables all over the world, and by the telephone! Few will be prepared to deny the statement that pure electrical science has received an enormous impulse, and has been advanced by the commercial application of electricity to the foregoing and to purposes of lighting. Since this latter application, scores, I may say hundreds, of acute minds have been devoted to electrical science, stimulated thereto by the possibilities and probabilities of this application.

In this country, no doubt, still more would have been done if the lighting of districts from a central source of electricity had not been since 1882 practically forbidden by the Act passed in that year. This Act had in its title the facetious statement that it was "to facilitate electrical lighting"—although it is an Act which, even modified as it has been this year, is still a great discouragement of free enterprise and a bar to progress. The other day a member of the House of Commons was saying to me: "I think it is very much to our discredit in England that we should have allowed ourselves to be outrun in the distribution of electric lighting to houses by the inhabitants of the United States, and by those of other countries." Looking upon him as being one of the authors of the "facetious" Act, I thought it pertinent to quote the case of the French parricide, who, being asked what he has to say in mitigation of punishment, pleads, "Pity a poor orphan"—the parricide and the legislator being both of them authors of conditions of things which they affect to deplore. I will say no more on this subject, for I feel that it would not be right to take advantage of my position here to-night to urge political economy views, which should be reserved for Section F. I will merely, and as illustrative of my views of the value of the application of science to science itself, say there is no branch of physics pursued with more zeal and with more happy results than that of electricity, with its allies, and there is no branch of science towards which the public looks with greater hope of practical benefits—a hope that, I doubt not, will be strengthened after we have had the advantage of hearing one of the ablest followers of that science, Prof. Ayrton, who on Friday next has been good enough to promise to discourse on "The Electrical Transmission of Power."

One of the subjects which, as much as (or probably more than) any other, occupies the attention of the engineer, and therefore of Section G, is that of (the so-called) prime movers; and I will say boldly that, since the introduction of printing by the use of movable type, nothing has done so much for civilisation as the development of these machines. Let us consider these prime movers; and, first, in the comparatively humble function of replacing that labour which might be performed by the muscular exertions of human beings—a function which at one time was looked upon by many kindly but short-sighted men as taking the bread out of the mouth of the labourer (as it was called), and as being, therefore, undesirable. I remember revisiting my old schoolmaster, and his saying to me, shaking his head: "So you have gone the way I always feared you would, and are making things of iron and brass to do the work of men's hands."

It must be agreed that all honest and useful labour is honourable; but when that labour can be carried out without the exercise of any intelligence, one cannot help feeling that the result is likely to be intellectually lowering. Thus it is a sorry thing to see unintelligent labour, even although that

Digitized by Google

labour be useful. It is but one remove from unintelligent labour which is not useful; that kind of labour generally appointed (by means of the tread-wheel or the crank) as a punishment for crime. Consider even the honourable labour (for it is useful and it is honest) of the man who earns his livelihood by turning the handle of a crane, and compare this with the labour of a smith, who, while probably developing more energy by the use of his muscles than is developed by the man turning the crane-handle, exercises at the same time the powers of judgment, of eye, and of hand in a manner which I never see without my admiration being excited. I say that the introduction of prime movers as a mere substitute for unintelligent manual labour is in itself a great aid to civilisation and to the raising of humanity, by rendering it very difficult, if not impossible, for a human being to obtain a livelihood by unintelligent work—the work of the horse in the mill, or of the turnspit.

But there are prime movers and prime movers—those of small dimensions, and employed for purposes where animal power or human power might be substituted, and those which attain ends that by no conceivable possibility could be attained at all by the exertion of muscular power.

Compare a galley—a vessel propelled by oars—with the modern Atlantic liner; and, first, let us assume that prime movers are non-existent, and that this vessel is to be propelled galley-fashion. Take her length as some 600ft., and assume that place be found for as many as 400 oars on each side, each oar worked by three men, or 2,400 men; and allow that six men, under these conditions, could develop work equal to 1 h.p.—we should have 400 h.p. Double the number of men, and we should have 800 h.p., with 4,800 men at work, and at least the same number in reserve, if the journey is to be carried on continuously. Contrast the puny result thus obtained with the 19,500 h.p. given forth by a large prime mover of the present day, such a power requiring, on the above mode of calculation, 117,000 men at work and 117,000 in reserve; and these to be carried in a vessel less than 600 feet in length. Even if it were possible to carry this number of men in such a vessel, by no conceivable means could their power be utilised so as to impart to it a speed of twenty knots an hour, weighing, as it would, some 10,500 tons gross.

This illustrates how a prime mover may not only be a mere substitute for muscular work, but may afford the means of attaining an end that could not by any possibility be attained by muscular exertion, no matter what money was expended, or what galley-slave suffering was inflicted.

Take, again, the case of a railway locomotive. From 400 to 600 h.p. developed in an implement which, even including its tender, does not occupy an area of more than fifty square yards, and that draws us at sixty miles an hour. Here, again, the prime mover succeeds in doing that which no expenditure of money or of life could enable us to obtain from muscular effort.

To what, and to whom, are these meritorious prime movers due? I answer: to the application of science, and to the labours of the civil engineer, using that term in its full and proper sense, as embracing all engineering other than military. I am, as you know, a civil engineer, and I desire to laud my profession and to magnify mine office; and I know of no better means of doing this than by quoting to you the definition of "civil engineering," given in the charter of the Institution of Civil Engineers—namely, that it is "the art of directing the great sources of power in Nature for the use and convenience of man." These words are taken from a definition or description of engineering given by one of our earliest scientific writers on the subject, Thomas Tredgold, who commences that description by the words above quoted, and who, having given various illustrations of the civil engineer's pursuits, introduces this pregnant sentence:

"This is, however, only a brief sketch of the objects of civil engineering, the real extent to which it may be applied is limited only by the progress of science; its scope and utility will be increased with every discovery in philosophy, and its resources with every invention in mechanical or chemical art, since its bounds are unlimited, and equally so must be the researches of its professors."

"The art of directing the great sources of power in Nature for the use and convenience of man." Among all secular pursuits can there be imagined one more vast in its scope, more beneficent, and therefore more honourable, than this? There are those, I know—hundreds, thousands—who say that such pursuits are not to be named as on a par with those of literature; that there is nothing ennobling in them; nothing elevating; that they are of the earth, earthy; are mechanical, and are unintellectual, and that even the mere bookworm, who, content with storing his own mind, neither distributes those stores to others, nor himself originates, is more worthily occupied than is the civil engineer.

I deny this altogether, and while acknowledging with gratitude that in literature the masterpieces of master minds have afforded, and will afford, instruction, delight, and solace for all generations so long as civilisation endures, I say that the pursuits of civil engineering are worthy of occupying the highest intelligence, and that they are elevating and ennobling in their character.

Remember the kindly words of Sir Thomas Browne, who said, when condemning the uncharitable conduct of the mere bookworm, "I make not, therefore, my head a grave, but a treasure of knowledge, and study not for mine own sake only, but for those who study not for themselves." The engineer of the present day finds that he must not make his "head a grave," but that, if he wishes to succeed, he must have, and must exercise, scientific knowledge; and he realises daily the truth that those who are to come after him must be trained in science, so that they may readily appreciate the full value of each scientific discovery as it is made. Thus the application of science by the engineer not only stimulates those who pursue science, but adds him to their number.

Holding, as I have said I do, the view that he who displaces unintelligent labour is doing good to mankind, I claim for the unknown engineer who, in Pontus, established the first water-wheel of which we have a record, and for the equally unknown engineer who first made use of wind for a motor, the title of pioneers in the raising of the dignity of labour, by compelling the change from the non-intelligent to the intelligent.

With respect to these motors—wind and water—we have two proverbs which discredit them: "Fickle as the wind," "Unstable as water."

Something more trustworthy was needed—something that we were sure of having under our hands at all times. As a result, science was applied, and the "fire" engine, as it was first called, the "steam" engine, as it was re-named, "a form of "heat" engine, as we now know it to be, was invented.

Think of the early days of the steam-engine—the pre-Watt days. The days of Papin, Savory, Newcomen, Smeaton! Great effects were produced, no doubt, as compared with no fire-engine at all; effects so very marked as to extort from the French writer, Belidor, the tribute of admiration he paid to the "fire" engine erected at the Fresnes Colliery by English engineers. A similar engine worked the pumps in York-place (now the Adelphi) for the supply of water to portions of London. We have in his work one of the very clearest accounts, illustrated by the best engravings (absolute working drawings) of the engine which had excited his admiration. These drawings show the open-topped cylinder, with condensation taking place below the piston, but with the valves worked automatically.

It need hardly be said that, noteworthy as such a machine was, as compared with animal power, or with wind or water motors, it was of necessity a most wasteful instrument as regards fuel. It is difficult to conceive in these days how, for years, it could have been endured that at each stroke of the engine the chamber that was to receive the steam at the next stroke was carefully cooled down beforehand by a water injection.

Watt, as we know, was the first to perceive, or, at all events, to cure, this fundamental error which existed prior to his time in the "fire" engine. To him we owe condensation in a separate vessel, the doing away with the open-topped cylinder, and the making the engine double-acting; the parallel motion; the governor; and the engine indicator, by which we have depicted for us the way in which the work is being performed within the cylinder. To Watt, also, we owe that great source of economic working—the knowledge of the expansive force of steam; and to his prescience we owe the steam jacket, without which expansion, beyond certain limits, is practically worthless. I have said "prescience"—fore-knowledge—but I feel inclined to say that, in this case, prescience may be rendered "pre-science," for I think that Watt *felt* the utility of the steam jacket, without being able to say on what ground that utility was based.

I have already spoken in laudatory terms of Tredgold, as being one of the earliest of our scientific engineering writers; but, as regards the question of steam jacketing, Watt's pre-science was better than Tredgold's science, for the latter condemns the steam jacket as being a means whereby the cooling surfaces are enlarged, and whereby, therefore, the condensation is increased.

I think it is not too much to say that engineers who, since Watt's days, have produced machines of such marvellous power—and, compared with the engines of Watt's days, of so great economy—have, so far as principles are concerned, gone upon those laid down by Watt. Details of the most necessary character—necessary to enable those principles to be carried out—have, indeed, been devised since the days of Watt. Although it is still a sad confession to have to make, that the very best of our steam-engines only utilises about one-sixth of the work which resides (if the term may be used) in the fuel that is consumed, it is, nevertheless, a satisfaction to know that great economical progress has been made, and that the 6lb. or 7lb. of fuel per h.p. per hour consumed by the very best engines of Watt's days, when working with the aid of condensation, is now brought down to about one-fourth of this consumption; and this in portable engines, for agricultural purposes, working without condensation—engines of small size, developing only 20 h.p.; in such engines the consumption has been reduced to as little as 1·85lb. per brake h.p. per hour, equal to 1·65lb. per

Digitized by Google

i.h.p. per hour, as was shown by the trials at the Royal Agricultural Society's meeting at Newcastle last year—trials in which I had the pleasure of participating.

In these trials, Mr. William Anderson, one of the vice-presidents of Section G, and I were associated; and, in making our report of the results, we adopted the balance-sheet system, which I suggested and used so long ago as 1873 (see vol. lii., pages 154 and 155 of the minutes of *Proceedings* of the Institution of Civil Engineers), and to which I alluded in my address as president of G, at Montreal.

I have told you that the engineer of the present day appreciates the value of the "next-to-nothings." There is an old housekeeping proverb that, if you take care of the farthings and the pence, the shillings and the pounds will take care of themselves. Without the balance-sheet, one knows that for the combustion of 1lb. of coal, the turning into steam of a given quantity of water at a given pressure is obtained. It is seen at once that the result is much below that which should be had, but to account for the deficiency is the difficulty. The balance-sheet, dealing with the most minute sources of loss—the farthings and the pence of economic working—brings you face to face with these, and you find that improvement must be sought in paying attention to the "next-to-nothings."

Just one illustration. The balance-sheet will enable you at a glance to answer this among many important questions. Has the fuel been properly burnt?—with neither too much air nor too little.

At the Newcastle trials our knowledge as to whether we had the right amount of air for perfect combustion was got by an analysis of the waste gases, taken continuously throughout the whole number of hours' run of each engine, affording, therefore, a fair average. The analysis of any required portion of gases thus obtained was made in a quarter of an hour's time by the aid of the admirable apparatus invented by Mr. Stead, and on the occasion to which I refer manipulated by him. In one instance an excess of air had been supplied, causing a percentage of loss of 6·34. In the instance of another engine there was a deficiency of air, resulting in the production of carbonic oxide, involving a loss of 4 per cent. The various percentages of loss, of which each one seems somewhat unimportant, in the aggregate amounted to 28 per cent., and this with one of the best boilers. This is an admirable instance of need of attention to apparently small things.

I have already said that we now know the steam-engine is really a heat-engine. At the York meeting of our Association I ventured to predict that, unless some substantive improvement were made in the steam-engine (of which improvement, as yet, we have no notion), I believed its days, for small powers, were numbered, and that those who attended the centenary of the British Association in 1931 would see the present steam-engines in museums, treated as things to be respected, and of antiquarian interest to the engineers of those days, such as are the open-topped steam-cylinders of Newcomen and of Smeaton to ourselves. I must say I see no reason, after the seven years which have elapsed since the York meeting, to regret having made that prophecy, or to desire to withdraw it.

The working of heat-engines, without the intervention of the vapour of water, by the combustion of the gases arising from coal, or from coal and from water, is now not merely an established fact, but a recognised and undoubted commercially economical means of obtaining motive power. Such engines, developing from 1 to 40 h.p., and worked by the ordinary gas supplied by the gas mains, are in most extensive use in printing works, hotels, clubs, theatres, and even in large private houses, for the working of dynamos to supply electric light. Such engines are also in use in factories, being sometimes driven by the gas obtained from "culm" and steam, and are giving forth a h.p. for, it is stated, as small a consumption as one pound of fuel per hour.

It is hardly necessary to remind you—but let me do it—that, although the saving of half a pound of fuel per h.p. appears to be insignificant when stated in that bald way, one realises that it is of the highest importance when that half-pound turns out to be 33 per cent. of the whole previous consumption of one of those economical engines to which I have referred.

The gas-engine is no new thing. As long ago as 1807, a M. de Rivaz proposed its use for driving a carriage on ordinary roads. For anything I know, he may not have been the first proposer. It need hardly be said that in those days he had not illuminating gas to resort to, and he proposed to employ hydrogen. A few years later, a writer in *Nicholson's Journal*, in an article on "flying machines," having given the correct statement that all that is needed to make a successful machine of this description is to find a sufficiently light motor, suggests that the direction in which this may be sought is the employment of illuminating gas, to operate by its explosion on the piston of an engine. The idea of the gas-engine was revived, and formed the subject of a patent by Barnett in the year 1838. It is true this gentleman did not know very much about the subject, and that he suggested many things which, if carried out, would have resulted in the production of an engine which could not have worked; but he had an alternative proposition which would have worked.

Again, in the year 1861 the matter was revived by Lenoir, and in the year 1865 by Hugon, both French inventors. Their engines obtained some considerable amount of success and notoriety, and many of them were made and used; but in the majority of cases they were discarded as wasteful and uncertain. The Institution of Civil Engineers, for example, erected a Lenoir in the year 1868 to work the ventilating fan, but after a short time they were compelled to abandon it, and to substitute an hydraulic engine.

At the present time, as I have said, gas-engines are a great commercial success, and they have become so by the attention given to small things, in popular estimation—to important things, in fact, with which, however, I must not trouble you. Messrs. Crossley Brothers, who have done so much to make the gas-engine the commercial success that it is, inform me that they are prosecuting improvements in the direction of attention to detail, from which they are obtaining greatly improved results.

But, looking at the wonderful petroleum industry, and at the multifarious products which are obtained from the crude material, is it too much to say that there is a future for motor-engines worked by the vapour of some of the more highly volatile of these products—true vapour—not a gas, but a condensable body, capable of being worked over and over again? Numbers of such engines, some of as much as 4 h.p., made by Mr. Yarrow, are now running, and are apparently giving good results—certainly excellent results as regards the compactness and lightness of the machinery. For boat purposes, they possess the great advantage of being rapidly under way. I have seen one go to work within two minutes of the striking of the match to light the burner.

Again, as we know, the vapour of this material has been used as a gas in gas-engines, the motive power having been obtained by direct combustion.

Having regard to these considerations, was I wrong in predicting that the heat-engine of the future will probably be one independent of the vapour of water? And, further, in these days of electrical advancement it is too much to hope for the direct production of electricity from the combustion of fuel?

As the world has become familiar with prime movers, the desire for their employment has increased. Many a householder could find useful occupation for a prime mover of ¼ or ½ h.p., working one or two hours a day; but the economical establishment of a steam-engine is not possible until houses of very large dimensions are reached, where space exists for the engine, and where, having regard to the amount of work to be done, the incidental expenses can be borne. Where this cannot be, either the prime mover, with the advantages of its use, must be given up as a thing to be wished for, but not to be procured, or recourse must be had to some other contrivance—say to the laying on of power in some form or another, from a central source.

I have already incidentally touched upon one mode of doing this—namely, the employment of illuminating gas, as the working agent in the gas-engine; but there are various other modes, possessing their respective merits and demerits—all ingenious, all involving science in their application, and all more or less in practical use—such as the laying-on of special high-pressure water, as is now being extensively practised in London, in Hull, and elsewhere. Water at 700lb. pressure per inch is a most convenient mode of laying on a large amount of power through comparatively small pipes. Like electricity, where, when a high E.M.F. is used, a large amount of energy may be sent through a small conductor, so with water, under high pressure, the mains may be kept of reasonable diameters without rendering them too small to transmit the power required through them

Power is also transmitted by means of compressed air, an agent which, on the score of its ability to ventilate, and of its cleanliness, has much to recommend it. On the other hand, it is an agent which, having regard to the probability of the deposition of moisture in the form of "snow," requires to be worked with judgment.

Again, there is an alternative mode for the conveyance of power by the exhaustion of air—a mode which has been in practical use for over sixty years.

We have also the curious system pursued at Schaffhausen, where quick-running ropes are driven by turbines, these being worked by the current of the river Rhine; and at New York, and in other cities of the United States, steam is laid on under the streets, so as to enable domestic steam-engines to be worked without the necessity of a boiler, a stoker, or a chimney, the steam affording also means of heating the house when needed.

Lastly, there is the system of transmitting power by electricity, to which I have already adverted. I was glad to learn, only the other day, that there was every hope of this power being applied to the working of an important subterranean tramway.

These distributions from central sources need, as a rule, statutory powers to enable the pipes or wires to be placed under the roads; and, following the deplorable example of the Electrical Facilities Act, it is now the habit of the enlightened corporation and the enterprising town clerk of most boroughs

Digitized by Google

to say to capitalists who are willing to embark their capital in the plant for the distribution of power from a central source—for their own profit, no doubt, but also, no doubt, for the good of the community—"We will oppose you in Parliament, unless you will consent that, at the end of twenty-one years, we may acquire compulsorily your property, and may do so, if it turns out to be remunerative, without other payment than that for the mere buildings and plant at that time existing." This is the way English enterprise is met, and then English engineers are taunted by Englishmen—often by the very men who have had a share in making this "boa-constrictor" of a "Facilities Act"—that their energy is not to be compared with that which is to be found in the United States and other countries. Again, however, I must remember that I am not addressing Section F.

There is one application of science, by engineers, which is of extreme beauty and interest, and that cannot be regarded with indifference by the agriculturists of this country. I allude to the heat-withdrawing engines (I should like to say, "cold-producers," but I presume, if I did, I should be criticised), which are now so very extensively used for the importation of fresh meat, and for its storage when received here. It need hardly be said, that that which will keep cool and sweet the carcases of sheep will equally well preserve milk and many other perishable articles of food. We have in these machines daily instances that, if you wish to make a ship's hold cold, you can do it by burning a certain quantity of coals—a paradox if ever there was one.

In this climate of ours, where the summer has been said to consist of "three hot days and a thunderstorm," there is hardly need to make a provision for cooling our houses, although there is an undoubted need for making a provision to heat them. Nevertheless, those of us who have hot-water heating arrangements for use in the winter would be very glad indeed if, without much trouble or expense, they could turn these about so as to utilise them for cooling their houses in summer. Mr. Loftus Perkins, so well known for his labours in the use of very high-pressure steam (600 to 1,000lb. on the inch), and also so well known for those most useful high-pressure warming arrangements which, without disfiguring our houses by the passage of large pipes, keep in a state of warmth and comfort throughout the winter, has lately taken up the mode of, I will say it, producing "cold" by the evaporation of ammonia, and, by improvements in detail, has succeeded in making an apparatus which, without engine or pumps, produces "cold" for some hours in succession, and requires, to put it in action, the preliminary combustion of only a few pounds of coke or a few feet of gas.

As I have said, our climate gives us but little need to provide or employ apparatus to cool our houses, but no one can well imagine that the Anglo-Indian will be glad to give up his punkah for some more certain, and less draughty, mode of cooling.

I now desire to point out how, as the work of the engineer grows, his needs increase. New material, or better material of the old kind, has to be found to enable him to carry out these works of greater magnitude. At the beginning of this century, stone, brick, and timber were practically the only materials employed for that which I may call standing engineering work—*i.e.*, buildings, bridges, aqueducts, and so on—while timber, cast iron, and wrought iron were for many years the only available materials for the framing and principal parts of moving machines and engines, with the occasional use of lead for the pipes and of copper for pipes and for boilers.

As regards the cast iron, little was known of the science involved (or that ought to be involved) in its manufacture. It was judged of by results. It was judged of largely by the eye. It was "white," it was "mottled," it was "grey." It was known to be "fit for refining," fit for "strong castings," or fit for castings in which great fluidity in the molten metal was judged to be of more importance than strength in the finished casting. With respect to wrought iron, it was judged of by its results also. It was judged of by the place of its manufacture; but when the works of the district were unknown, the iron, on being tested, was classed as "good fibrous," although some of the very best was "steel-like," or "bad," "hot-short," or "cold-short." A particular district would produce one kind of iron, another district another kind of iron. The ore, the flux, and the fuel were all known to have influence, but to what extent was but little realised; and if there came in a new ore, or a new flux, it might well be that for months the turn-out of the works into which these novelties had been introduced would be prejudiced. Steel again—that luxury of the days of my youth—was judged by the eye. The wrought bars, made into "blister" steel by "cementation," were broken, examined, and grouped accordingly. Steel was known, no doubt, to be a compound of iron and carbon, but the importance of exactness in the percentage was but little understood, nor was it at all understood how the presence of comparatively small quantities of foreign matter might necessitate the variation of the proportions of carbon. The consequence was that anomalous results every now and then arose to confound the person who had used the steel, and, falsifying the proverb "true as steel," steel became an object of distrust. Is it too much to say that Bessemer's great invention of steel made by the "converter" and that Siemens' invention of the open-hearth process reacted on pure science, and set scientific men to investigate the laws which regulate the union of metals and of metalloids? and that the labours of these scientific men have improved the manufacture, so that steel is now thoroughly and entirely trusted? By its aid engineering works are accomplished which without that aid would have been simply impossible. The Forth Bridge, the big gun, the compound armour of the ironclad, with its steel face, the projectile to pierce that steel face—all equally depend upon the "truth" of steel as much as does the barely visible hair-spring of the chronometer, which enables the longitude of the ship in which it is carried to be ascertained. Now what makes the difference between trustworthy and untrustworthy steel for each particular purpose? Something which, until our better sense comes to our aid, we are inclined to look upon as ridiculously insignificant—a "next-to-nothing." Setting extraneous ingredients aside, and considering only the union of iron and carbon, the question whether there shall be added or deducted one-tenth of one per cent. (pardon my clumsy way of using the decimal system) of carbon is a matter of great importance in the resulting quality of the steel. This is a striking practical instance of how apparently insignificant things may be of the highest importance. The variation of this fraction of a percentage may render your boiler steel untrustworthy, may make the difference between safety in a gun and danger in a gun, and may render your armour-piercing projectile unable to pierce even the thinnest wrought-iron armour.

While thus brought incidentally to the subject of guns, let me derive from it another instance of the value of small things. I have in my hand a piece of steel ribbon. It is probable that only those who are near to me can see it. Its dimensions are one-fourth by one-sixteenth of an English inch, equal to an area of one sixty-fourth of a square inch. This mode of stating the dimensions I use for the information of the ladies. To make it intelligible to my scientific friends, I must tell them that it is approximately ·00637 of a metre, by approximately ·00159 of a metre, and that its sectional area is ·0000101283 (also approximately) of a square metre. This insignificant and (speaking in reference to the greater number of my audience) practically invisible piece of material—that I can bend with my hand, and even tie into knots—is, nevertheless, not to be despised. By it one reinforces the massive and important-looking A-tube of a 9·2-in. gun, so that from that tube can be projected with safety a projectile weighing 380lb. at a velocity, when leaving the muzzle, of between one-third and one-half of a mile in a second, and competent to traverse nearly 12½ miles before it touches the ground. It may be said, "What is the use of being able to fire a projectile to a distance which, commonly, is invisible—from some obstacle or another—to the person directing the gun?" I will suggest to you a use. Imagine a gun of this kind placed by some enemy who unfortunately had invaded us, and had reached Richmond. He has the range table for his gun; he, of course, is provided with our ordnance maps, and he lays and elevates the gun at Richmond with the object of striking, say, the Royal Exchange. Suppose he does not succeed in his exact aim. The projectile goes 100 yards to one side or to the other, or it falls 250 yards short or passes 250 yards over; and it would be "bad shooting" indeed, in these days, if nearly every projectile which was fired did not fall somewhere within an area such as this. In this suggested parallelogram of 100,000 square yards, or some 20 acres, there is some rather valuable property; and the transactions which are carried on are not unimportant. It seems to me that business would not be conducted with that calmness and coolness which are necessary for success, if, say every five minutes, a 380-pound shell fell within this area, vomiting fire, and scattering its walls in hundreds of pieces, with terrific violence, in all directions. Do not suppose I am saying that similar effects cannot be obtained from a gun where wire is not employed. They can be. But my point is, that they can also be obtained by the aid of the insignificant thing which I am holding up at this moment—this piece of steel ribbon, which looks more suitable for the framework of an umbrella.

I have already spoken to you, when considering steel as a mere alloy of iron, as to the value of even a fraction of 1 per cent. of the carbon; but we know that in actual practice steel almost always contains other ingredients. One of the most prominent of these is manganese. It had for years been used, in quantities varying from a fraction of 1 per cent. up to 2·5 per cent., with advantage as regards ductility, and as regards its ability to withstand forging. A further increase was found not to augment the advantage; a still further increase was found to diminish it, and here the manufacturer stopped; and, so far as I know, the pure scientist stopped, on the very reasonable ground that the point of increased benefit appeared to have been well ascertained, and there could be no advantage in pursuing an investigation which appeared only to result in decadence. But this is another instance of how the application

Digitized by Google

of science reacts in the interests of pure science itself. One of our steel manufacturers, Mr. Hadfield, determined to pursue this apparently barren subject, and in doing so discovered this fact—that, while with the addition of manganese in excess of the limit before stated, and up to as much as 7 per cent. deterioration continued, after this latter percentage was passed improvement again set in.

Again, the effects of the addition of even the very smallest percentages of aluminium upon the steel with which it may be alloyed are very striking and very peculiar, giving to the steel alloy thus produced a very much greater hardness, and enabling it to take a much brighter and more silver-like polish. Further, the one-twentieth part of 1 per cent. of aluminium, when added to molten wrought iron, will reduce the fusing-point of the whole mass some 500 degrees, and will render it extremely fluid, and thus enable wrought iron (or what are commercially known as "Mitis"—castings of the most intricate character) to be produced.

No one has worked more assiduously at the question of the effect of the presence of minute quantities, even traces of alloys with metals, than Prof. Roberts-Austen, and he appears, by his experiments, to be discovering a general law governing the effect produced by the mixture of particular metals, so that, in future, it is to be hoped, when an alloy is for the first time to be attempted, it will be possible to predict with reasonable certainty what the result will be, instead of that result remaining to be discovered by experiment.

I have just, incidentally, mentioned aluminium. May I say that we engineers look forward with much interest to all processes tending to bring this metal, or its alloys, within possible commercial use?

One more instance of the effect of impurities in metals. The engineer engaged in electrical matters is compelled, in the course of his daily work, frequently to realise the importance of the "next-to-nothing." One striking instance of this is afforded by the influence which an extremely minute percentage of impurity has on the electrical conductivity of copper wire; this conductivity being in some cases reduced by as much as 50 per cent., in consequence of the admixture of that which, under other circumstances, would be looked upon as insignificant.

Reverting to the question of big guns. According to the present mode of manufacture, after we have rough-bored and turned the "A" tube (and perhaps I ought to have mentioned that by the "A" tube is meant the main piece of the gun, the innermost layer, if I may so call it, that portion which is the full length of the gun, and upon which the remainder of the gun is built up)—after, as I have said, we have rough-bored and turned this "A" tube, we heat it to a temperature lying between certain specified limits, but actually determined by the behaviour of samples previously taken, and then suddenly immerse it perpendicularly into a well some 60ft. deep, full of oil, the oil in this well being kept in a state of change by the running into it, at the bottom, of cold oil, conveyed by a pipe proceeding from an elevated oil tank. In this way the steel is oil-hardened, with the result of increasing its ultimate tensile strength, and also with the result of raising its so-called elastic limit. In performing this operation it is almost certain that injurious internal strains will be set up: strains tending to produce self-rupture of the material. Experiments have been carried out in England, by Captain Andrew Noble, and by General Maitland of the Royal Gun Factory, by General Kalakoutsky, in Russia, and also in the United States, to gauge what is the value, as represented by dimensions, of these strains, and we find that they have to be recorded in the most minute fractions of an inch, and yet, if the steel be of too "high" a quality (as it is technically called), or if there has been any want of uniformity in the oil-hardening process, these strains, unless got rid of or ameliorated by annealing, may, as I have said, result in the self-rupture of the steel.

I have spoken of the getting rid of these strains by annealing, a process requiring to be conducted with great care, so as not to prejudice the effects of the oil-hardening. But take the case of a hardened steel projectile, hardened so that it will penetrate the steel face of compound armour. In that case annealing cannot be resorted to, for the extreme hardness of the projectile must not be in the least impaired. The internal strains in these projectiles are so very grave, that for months after they are made there is no security that they will not spontaneously fracture. I have here the point of an 8in. projectile, which projectile weighs 210lb. This, with others, was received from the makers as long ago as March of this year, and remained an apparently perfect and sound projectile until about the middle of August—some five months after delivery—and, of course, a somewhat longer time since manufacture; and between August 6th and 8th this piece which I hold in my hand, measuring 3¾in. by 3½in., spontaneously flew off from the rest of the projectile, and has done so upon a surface of separation which, whether having regard to its beautiful regularity, or to the conclusions to be drawn from it as to the nature of the strains existing, is of the very highest scientific interest. Many other cases of self-rupture of similar projectiles have been recorded.

Another instance of the effect of the "next-to-nothing" in the hardening and tempering or annealing of steel. As we know, the iron and the carbon (leaving other matters out of consideration) are there. The carbon is (even in tool steel) a very small proportion of the whole. The steel may be bent, and will retain the form given to it. You heat it, and plunge it in cold water; you attempt to bend it, and it breaks; but if, after the plunging in cold water, you temper it by carefully reheating it, you may bring it to the condition fit either for the cutting-tool for metal or for the cutting-tool for wood, or for the watch-spring; and these important variations of condition which are thus obtained depend upon the "next-to-nothing" in the temperature to which it is reheated, and, therefore, in the nature of the resulting combination of the ingredients of which the steel is composed.

Some admirable experiments were carried out on this subject by the Institution of Mechanical Engineers, with the assistance of one of our vice-presidents, Sir Frederick Abel, and the subject has also been dealt with by an eminent Russian writer.

There is, to my mind, another and very striking popular instance (if I may use the phrase) of the importance of attention to detail—that is, to the "next-to-nothing." Consider the bicycles and tricycles of the present day—machines which afford the means of healthful exercise to thousands, and which will probably within a very short time prove of the very greatest possible use for military purposes. The perfection to which these machines have been brought is almost entirely due to strict attention to detail; in the selection of the material of which the machines are made; in the application of pure science (in its strictest sense) to the form and to the proportioning of the parts, and also in the arrangement of these various parts in relation the one to the other. The result is that the greatest possible strength is afforded with only the least possible weight, and that friction in working has been reduced to a minimum. All of us who remember the hobby-horse of former years, and who contrast that machine with the bicycle or tricycle of the present day, realise how thoroughly satisfactory is the result of this attention to detail—this appreciation of the "next-to-nothing."

Let me give you another illustration of the importance of small things, drawn from gunnery practice.

At first sight one would be tempted to say that the density of the air on the underside of a shot must, notwithstanding its motion of descent, be so nearly the same as that of the air upon the upper side as to cause the difference to be unworthy of consideration, but we know that the projectiles from rifled guns tend to travel sideways as they pass through the air, and that the direction of their motion, whether to the right or to the left, depends on the "hand" of the rifling. We know also that the friction against liquid or against gaseous bodies varies with the densities of these bodies, and it is believed that, minute as is the difference in density to which I have referred, it is sufficient to determine the lateral movement of the projectile. This lateral tendency must be allowed for, in these days of long ranges, in the sighting and laying of guns, if we desire accuracy of aim, at those distances at which it is to be expected our naval engagements will have to be commenced, and perhaps concluded. We can no longer afford to treat the subject as Nelson is said to have treated it in one of his letters to the Secretary of the Admiralty, who had requested that an invention for laying guns more accurately should be tried. Nelson said he would be glad to try the invention, but that as his mode of fighting consisted in placing his ship close alongside that of the enemy, he did not think the invention, even if it were successful, would be of much use to him.

While upon the question of guns, I am tempted to remark upon that which is by no means a small thing (for it is no less than the rotation of the earth), which in long-distance firing may demand attention, and that to an extent little suspected by the civilian.

Place the gun north and south, say in the latitude of London, and fire a twelve-mile round such as I have mentioned, and it will be found that, assuming the shot were passing through a vacuum, a lateral allowance of more than 200ft. must be made to compensate for the different velocity of the circumference of the earth at twelve miles north or south of the place where the gun was fired, as compared with the velocity of the circumference of the earth at that place itself—the time of flight being in round numbers one minute.

At the risk of exciting a smile, I am about to assert that engineering has even its poetical side. I will ask you to consider with me whether there may not be true poetry in the feelings of the engineer who solves a problem such as this: Consider this rock, never visible above the surface of the tide, but making its presence known by the waves which rise around it: it has been the cause of destruction to many a noble vessel which had completed, in safety, its thousands of leagues of journey, and was within a few score miles of port; then dashed to pieces upon it? Here is this rock. On it build a lighthouse. Lay your foundations through the water, in the midst of the turmoil of the sea; make your preparations; appear to be attaining success, and find the elements are against you, and that the

Digitized by Google

whole of your preliminary works are ruined or destroyed in one night; but again commence, and then go on and go on until at last you conquer; your works rise above ordinary tide-level; then upon these sure foundations, obtained it may be after years of toil amid the poetical surroundings I have indicated, erect a fair shaft, graceful as a palm and sturdy as an oak; surmount it with a light, itself the produce of the highest application of science; direct that light by the built-up lens, again involving the highest application of science; apply mechanism, so arranged that the lighthouse shall from minute to minute reveal to the anxious mariner its exact name and its position on the coast. When you have done all this, will you not be entitled to say to yourself, "It is I who have for ever rendered innocuous this rock which has been hitherto a dread source of peril?" Is there no feeling, do you think, of a poetical nature excited in the breast of the engineer who has successfully grappled with a problem such as this?

Another instance; the mouth of a broad river, or, more properly speaking, the inlet of the sea, has to be crossed at such a level as not to impede the passage of the largest ships. Except in one or two places the depth is profound, so that multiple foundations for supporting a bridge become commercially impossible, and the solution of the problem must be found by making, high in the air, a flight of span previously deemed unattainable. Is there no poetry here? Again, although the results do not strike the eye in the same manner, is there nothing of poetry in the work, that has to be thought out and achieved, when a wide river or an ocean channel has to be crossed by a subterranean passage. Works of great magnitude of this character have been performed with success, and to the benefit of those for whose use they were intended. One of the greatest and most noble of such works, encouraged, in years gone by, by the Governments of our own country and of France, has lately fallen into disfavour with an unreasoning public, who have not taken the pains to ascertain the true state of the case.

Surely it will be agreed that the promotion of ready intercourse and communication between nations constitute the very best and most satisfactory guarantees for the preservation of peace; when the peoples of two countries come to know each other intimately, and when they, therefore, enter into closer business relations, they are less liable to be led away by panic or by anger, and they hesitate to go to war the one with the other. It is in the interests of both that questions of difference which may arise between them should be amicably settled, and having an intimate knowledge of each other, they are less liable to misunderstand, and the mode of determination of their differences is more readily arranged. Remember, the means of ready intercourse and of communication, and the means of easy travel, are all due to the application of science by the engineer. Is not, therefore, his profession a beneficent one?

Further, do you not think poetical feeling will be excited in the breast of that engineer, who will in the near future solve the problem (and it certainly will be solved when a sufficiently light motor is obtained) of travelling in the air—whether this solution be effected by enabling the self-suspended balloon to be propelled and directed—or, perhaps, better still, by enabling not only the propulsion to be effected and the direction to be controlled, but by enabling the suspension in the air itself to be attained by mechanical means?

Take other functions of the civil engineer—functions which, after all, are of the most important character, for they contribute directly to the prevention of disease, and thereby not only prolong life, but do that which is probably more important—afford to the population a healthier life while lived.

In one town, about which I have full means of knowing, the report has just been made that in the year following the completion of a comprehensive system of sewerage, the deaths from zymotic diseases had fallen from a total of 740 per annum to a total of 372—practically one half. Has the engineer no inward satisfaction who knows such results as these have accrued from his work?

Again, consider the magnitude and completeness of the water supply of a large town, especially a town that has to depend upon the storing-up of rain water; the provision which takes into account, not merely the variation of the different seasons of the year, but the variation of one year from another; that, having collated all the stored-up information, determines what must be the magnitude of the reservoirs to allow for at least three consecutive dry years, such as may happen; and that finds the sites where these huge reservoirs may be safely built.

All these—and many other illustrations which I could put before you if time allowed—appear to me to afford conclusive evidence that, whether it be in the erection of the lighthouse on the lonely rock at sea; whether it be in the crossing of rivers or seas, or arms of seas, by bridges or by tunnels; whether it be the cleansing of our towns from that which is foul; whether it be the supply of pure water to every dwelling, or the distribution of light or motive power; or whether it be in the production of the mighty ocean steamer, or in the spanning of valleys, the piercing of mountains, and affording the firm, secure road for the express train; or whether it be the encircling of the world with telegraphs—the work of the civil engineer is not of the earth earthy, is not mechanical to the exclusion of science, is not unintellectual; but is of a most beneficent nature, is consistent with true poetical feeling, and is worthy of the highest order of intellect.

THE PROTECTION OF ELECTRIC LIGHT STATIONS FROM LIGHTNING.

BY W. J. JENKS.

(*Continued from page 188.*)

Perhaps the most vital portion of any street system of lightning protection is the connection established beneath the surface of the earth. If we proceed upon the basis of the theory of powerful attraction to localities or lines of electric tension, it is essential that we either connect directly with these channels or terminate our conductors so that the descending charge shall reach them by the most direct way possible.

Imperfect Ground Connections.—In 1878, before the days of cheap magneto call-bells, I had occasion to connect the shooting station of a 1,000-yard rifle range with the markers' pit at the targets by a telephone line. The wire was No. 12 iron, substantially erected on poles. The ground at the shooting shed, a plate 1ft. or 2ft. square, in a small stream, was undoubtedly good. After passing over the 3,000ft. interval and through the target instruments, the line was carefully connected with an inch iron bar driven from 3ft. to 4ft. into the ground at the bottom of the pits. To my amazement, four freshly-made Daniell cells failed to operate a single 25-ohm tap bell over this line. Four more showed no better result. A third instalment, making twelve in all, wouldn't make the bell wink. A second iron rod was added, and both together driven into the clayey soil failed to operate. Another branch to a third rod a hundred feet down the side hill was likewise ineffectual. Any one of them would work the telephone, but we had to run a return wire back to the station to make a reliable circuit, and then the two bells were easily operated over the 6,000ft. of wire with two cells of battery. The entire slope, perhaps the tree-crowned hill behind it, was highly insulated from the arteries leading to the electrical reservoir below.

There are whole valleys in the Lake Superior copper region thus electrically isolated from the earth's channels, and it is said that lightning has never been known to strike them.

A noted European electrician who spent years in cable work once told me a story almost incredible as to this peculiar condition of localities on the earth surface. A trans-Atlantic cable has been laid on an island off the Irish coast, and here the repeating station was to be placed—the point where the language of the shadow signs, or the syphon recorder is translated into Morse dots and dashes. The usual ground-plate of copper, about 5 or 6 square feet, had been buried in the scanty soil which bounded the rocky coast. The battery was applied, but no signal went out. Beyond question, the cable itself was perfect. Another plate of 10 square feet was buried, just above low-water mark, in the sand. This gave a current so faint that it could barely be perceived. Still another plate 6ft. square (36 square feet in area—or, on both sides, 72 square feet of exposed surface) was covered 3ft. deep in sand and mud. Still no practical result. The expert was staggered. Delicate Thomson galvanometers were barely deflected by a hair's breadth. In disgust he tried once more, this time taking several pounds of shingle nails, and, uncovering the broad face of the copper sheet, drove the nails through, about half an inch apart, over its entire surface. Then, the hundreds of nail points and thousands of minute slivers and crystalline faces of copper exposed to contact with the earth and water made a connection of so low resistance that the current flowed freely through with perfect results.

One more illustration from telephone experience. In 1880 the American Bell Telephone Company began to license the construction of "extra-territorial" lines, connecting widely separated exchanges. One of the first was built for the Inter-State Telephone Company from Boston, the cradle of the telephone industry, to Providence, by

*Abstract of paper read before the Association of Edison Companies.

Digitized by Google

wire 50 miles. The construction was most substantial, and it was expected that in a short time the magnificent line of 40ft., 50ft., and 60ft. poles would carry the 50 wires which were provided for. It was at that time a theory with the "experts" that interference or cross-talk was merely leakage, and so to carry away the currents which by any means might creep over the glass and its support, a sheet-iron collar was arranged to surround the base of each pin and connect with a wire under the cross arm, joining another leading down from the point of the pole and winding several times around its base. Here it was supposed to make a perfect earth connection. Measurements showed the resistance of these grounds to be all the way from 100 to 3,000 ohms each. Occasionally, where the soil was very wet, the results would be better, and of course even the worst of such grounds will avoid the destruction of the pole by the splintering from top to bottom which often occurs where the current can find no better conductor than the moisture in the pores of the wood.

Whatever may be the retarding influence of poor conductors upon the intensity or explosive action of a discharge, it is certain that at all times the duration of the lightning flash is inconceivably short. This is illustrated by the fact that the rapidly revolving spinning-wheel is seen by the lightning flash as if perfectly stationary. Wheatstone estimated that the lightning flash occupied less than one-millionth part of a second. As the full effect of any sudden light upon the eye requires one-tenth of a second, it is plain that we can neither appreciate the almost infinite velocity of the current nor the brilliancy of the illumination. Were the lightning permanent, the apparent brightness would probably be one hundred thousand times greater than we now experience.

Hence, the common statement that the direction of the spark can be seen is plainly incorrect, and must arise from the optical illusion excited by the greater sensitiveness of the central parts of the eye. Hence, the point seen directly in front of the eye affects the brain sooner than the rest.

Everthing points to the reasonableness of the idea that, other things being equal, certain lines or points beneath the surface strive to interchange their energy with the points of the clouds most densely charged, and will do it in straight lines unless some tremendous resistance is set up by an insulating material, or by the action of the rush of current upon the conductors in its way. A vast system of water pipes, which affords the best possible ground connection for all circuits of low pressure, sometimes proves entirely inadequate to discharge the tremendous energy of the thunder cloud without a rupture of the iron mains.

A flash that finds its way from a small wire into a network of iron pipes may, in leaving that network at a certain point of maximum attraction, rend the metal asunder with an explosive force which we can only estimate, and cause disastrous effects in the system. These, of course, are the exceptions.

Gas-pipes should not, under any circumstances, be used as grounds, except as connection may be made outside the meter; in fact, outside of all joints within buildings, because the leaded joints themselves are likely to offer resistance, and induce a spark which may fire the gas, or a melting action which may entirely open the pipe, and cause the firing of combustible material. A melting out of the meters is often traceable to this cause.

One of the best earth connections may generally be made by a copper plate from 3 to 6 square feet in area, so placed at the bottom of a well that it will come into intimate contact with the soil itself. Another very desirable form may be arranged by burying a large quantity of grey retort carbon or charcoal in damp soil, and this again may be still further improved by leading to this bed of carbon a water spout from the roof. In many cases it is possible to get a most desirable form of ground connection by burying a large plate at the terminus of a drain or in the bed of a stream. That the stream, alone, however, cannot be relied upon as affording a distributing channel has been more than once demonstrated. Here is an illustration of an instance which came under my own observation. A forest tree was struck and partially shattered, the charge leaving its trunk some six feet from the earth, running along the surface, deliberately jumping a stream at least six feet in width and ploughing up the earth beyond for some distance, finally boring a hole vertically over what was presumably a subterranean water course, or similar line of attraction.

(To be concluded.)

THE AUSTRALIAN CABLES.

BY W. J. HANCOCK, M.S.T.E.

The Australian Duplicate Cable line branches off from the Eastern Extension Telegraph Company's extensive system at Singapore. Messages by the old cable go from Singapore to Batavia; and from Batavia across Java to Barjoewangie, thence by a cable which skirts the islands of Sumbawa, Flores, and Timor, and passes to the South of Sumba or Sandalwood Island.

The second cable goes from Singapore to Banjoewangie direct, and on again to Port Darwin. This cable goes to the north of all these islands, and lies in deep water. The greatest distance between the two cables is off Sunda Island, where they are about 100 miles apart.

The first cable was laid by the Eastern Extension Telegraph Co., unsubsidised, in 1871, and before the overland telegraph line to Port Darwin was finished; the messages being conveyed by horse express over the unfinished portion until the 21st of October, 1872, when through telegraphic communication was first established.

The advantage of rapid communication with the rest of the world was found to be so great that when interruptions occasionally occurred involving loss and inconvenience, the question of duplicating the cable was seriously considered, the result being that a second cable was laid between Singapore and Port Darwin in 1879 by the same company, the colonies of Victoria, South Australia, New South Wales, and Western Australia jointly paying, in proportion to their respective populations, an annual subsidy of £34,400 for a period of 20 years.

The conductor of the 1871 cable consists of seven stranded copper wires, of about No. 20 B.W. gauge each, surrounded with several layers of gutta-percha composition, forming the insulation. This is again encased in an armour consisting of iron wires, to protect and give the necessary strength to the cable. This is finally wound with hemp and asphalte. The shore ends of the cable are more heavily protected by very much thicker wires. The main cable is about 1in. in diameter, and weighs 3½ tons to the mile, while the shore ends weigh about 11½ tons per mile.

The 1879 cable is very similar, except that an intermediate size of cable is used, as well as the main and shore cable. The shore end of this cable weighs about 10 tons, intermediate 3½, and main 1¼ tons per mile. In this cable, between the gutta-percha core and the iron wires, brass tape is wound as a protection against the attacks of the teredo navalis, a little worm that bores through the gutta-percha, thereby destroying the insulation. These cables cost, roughly, about £100 per mile.

The system adopted for working is not the same as is used for ordinary telegraph lines, in which direct currents are transmitted. The submarine cable is analogous to an immense and attenuated Leyden jar, or condenser, the conductor being the inner, the sheath and water the outer coating, and the gutta-percha acting as the glass insulator. Thus the cable, so to speak, holds a charge of electricity, and by varying the amount and polarity of this charge, according to a preconcerted arrangement of signals, the messages can be signalled.

The instrument generally used on a long cable is Sir W. Thomson's syphon recorder, which consists of a coil of very fine wire, suspended between the poles of two powerful electro-magnets. Through this coil of wire the currents received travel. Fixed to this coil is a very fine glass syphon tube, which conducts the ink from the reservoir to a strip of paper drawn past the end of the glass tube at a uniform speed. Thus this glass pen records every movement of the coil to right or left. The suspended coil and tube will be attracted towards one electro-magnet or the other according to the polarity and strength of the current received. Thus, it will be easily understood how a code of signals can be made to represent the alphabet, as in the international code, letters are represented by movements of the coil and glass tube, which are recorded on the paper strip. Thus, A is represented by one movement to right and one to left. B one to the right, three to the left; C, one right one left, one right one left, and so on.

The speed of the instrument on the newest cables is about 18 words of five letters each per minute, but when worked duplex the rate is about doubled. Cable working is slow compared with the ordinary telegraph, which varies from 25 to 40 words when worked by hand, to from 200 to 1,000 per minute in various rapid automatic machines.

When a cable is broken, one way of finding the distance of the break is approximately as follows: The resistance which the entire length of the conductor of the cable offers to the passage of the electric current is known, and tests are usually taken each morning before work. The unit of resistance is called the "ohm." Thus the resistance of the 1879 cable is about 13,000 ohms, or about 11½ ohms per mile, in good condition. When the cable is broken and the inside conductor exposed, the current has not got to travel the entire length, but only as far as the break, and back by the iron sheathing and water, the resistance of which is taken as nil. The resistance is now much less, and from the testing instrument the number of ohms can be found, and as so many miles go to one ohm the number of miles distance of the fault is calculated. The matter is, however, not so simple, as various circumstances occur which interfere with the result. For instance, a small portion of the conductor may be exposed, a local current set up between the copper and iron wires in the sea water, polarisation, and other troubles.

To fish up the cable, a grapnel and stout wire rope is used, the

Digitized by Google

steamer going slowly across the line of the cable, until it is caught, when it is hauled on board, examined, and repaired.

The course of telegraphic messages from Perth to London is as follows:

	Miles of Land Line.	Miles of Cable.	Total.
Perth-Albany	261	—	261
Albany-Eucla	762	—	752
Eucla-Port Augusta	759	—	759
Port Augusta-Alice Springs	1036	—	1036
Alice Springs-Port-Darwin	898	—	898
Port Darwin-Banjoewangie	—	1150	1150
Banjoewangie-Batavia	480	—	480
Batavia-Singapore	—	553	553
Singapore-Penang	—	399	399
Penang-Madras	—	1280	1280
Madras-Bombay	650	...	650
Bombay-Aden	—	1662	1662
Aden-Suez	—	1346	1346
Suez-Alexandria	224	—	224
Alexandria-Malta	—	828	828
Malta-Gibraltar	—	1008	1008
Gibraltar-Falmouth	—	1061	1061
Falmouth-London	350	—	350
	5,410	9,287	14,697

In the event of interruption of the cable connections at certain points of the regulated route, messages can be sent by way of Penang or Rangoon, or viâ Saigon, Bankok, and Tavoy (Burmah), or by the Indo-European Company's system, through Russia and across Europe, or by the Great Northern Company's system, across Siberia. This last route is as follows:

	Miles.
Singapore to Hong Kong	1876
Hong Kong to Shanghai	1265
Shanghai to Posiett Bay, Siberia	1380
Across Siberia and Russia, to Lieban, Baltic	6394
Lieban to New Beggin, England	1656
Total	12,571

The distance by the proposed route across Canada is approximately

Sydney to Vancouver, B. Columbia	8900
Across Canada	3400
Canada to Ireland	2450
Total	14,800

Messrs. Millar Bros.' proposed cable from the North-West Coast of Australia would be

N.W. Coast of Australia to Madras	3500
Madras to London	8409
	11,909

This would have the advantage of avoiding the volcanic regions through which both the present cables run.

The break in the cable communication may be caused by some of those violent volcanic disturbances which occur so frequently in the neighbourhood of the Malay Archipelago.

According to the latest test, the distance of the break is about 858 miles from Port Darwin on the old line, and on the new cable 898 miles. The commander of the "Myrmidon" reports that Mount Tomboro is in active eruption. This troublesome volcano is on the north side of Sumbawa Island. To the south of this island lie both cables, not very far apart. This point is, however, about 900 miles from Port Darwin, and about 200 miles from Banjoewangie. That the old cable was previously defective, and the new cable suddenly from some cause failed, thus cutting off all communication, is probably the most reasonable explanation.

If the cables are only broke in one place, a steamer would not take long to pick them up and repair the damage. But if much of the cable has been destroyed by violent disturbance over a considerable area (similar to what occurred in 1882 at Krakatoa) new pieces will have to be put in, and unless the cable steamers (one of which was reported to have been at Shanghai and the other at New Zealand) on their return have sufficient length to repair the damage, or unless a piece of the old cable is cut out, and spliced into the new one, or *vice versa*, some months may elapse before through telegraph communication will be restored.

But it is utterly impossible to foretell how long the break may last, as it depends on the damage, the cause of which we have no means of knowing at present, shut out as we are from the rest of the world.

The present cost of cablegrams from Perth to London is as follows:

Public message *via* Europe direct, 9s. 4d. per word of 10 letters; Cochin China, 12s 2d.; Hong Kong and Siberia, 15s. 1d.

During the year 1886, 46,667 messages to and from Australasia passed through the Port Darwin cables, representing £256,527, or an average per message of £5. 10s.

NEW COMPANIES REGISTERED.

Barnet and District Electric Supply Company, Limited.—Registered by Messrs. Ingledew, Ince, and Colt, of St. Benet-chambers, Fenchurch-street, with a capital of £5,000, divided into 490 ordinary shares of £10 each, and 100 founder's shares of £1 each. The object is to purchase all rights, benefits, &c., of Henry Francis Joel, under a contract of the Barnet Local Board, for the lighting of the district by electricity, and the supply of electricity to shops, &c. The first list of shareholders includes Mr. J. Ross, Basinghall-street; Mr. J. Palmer, Finsbury-square; and Mr. H. F. Joel, Wilson-street.

"Rees" Miners' Patent Safety Electric Lamp Company, Limited.—This Company has been registered to acquire, under an agreement already prepared and intended to be executed immediately after the incorporation of the Company, and to be made between John Price Rees of the one part, and Thomas M. Field, as trustee for the Company, of the other part, with such (if any) modifications as may be agreed upon certain letters patent obtained for the United Kingdom and elsewhere of the "Rees" Miners' Patent Safety Electric Lamp and the "Rees" Double Liquid Primary Battery and all future improvements, and any extension of the same. The capital of the Company is £50,000, divided into 10,000 shares of £5 each.

Bedford Electric Light Company, Limited.—Registered by Richard Jordan, 120, Chancery-lane, W.C., with a capital of £15,000, in shares of £1 each. Object: to enter into contracts for electric lighting, either alone or in conjunction with other means, and for the supply of electric energy for power or transmission, and for fixing, maintaining, sealing, hiring or otherwise dealing with transformers, wires, lamps, primary, secondary or storage batteries, and all other electrical appliances and equipments with any corporation or person, and to supply or manufacture, purchase or hire, take in, exchange or otherwise acquire, sell and supply all machinery, motors, generators, lamp materials, or appliances in connection with the production, transmission, storage and use by any means and any purpose of light and heat, and electric, magnetic or other force. The first subscribers are:

	Shares.
Sir H. Mance, Menora, Newnham-road, Bedford	1
T. Jessop, St. Paul's-square, Bedford	1
R. B. Stafford, Cauldwell House, Bedford	1
W. B. Jessop, 3, St. Paul's-square, Bedford	1
O. T. Christie, Hoddesden, Herts	1
T. Spencer, Ashburnham-road, Bedford	1
D. Bower, Springfield House, near Bedford	1

The number of Directors shall not be less than three, and the first Directors shall be appointed by the signatories to the memorandum of association. The qualification of every Director shall consist of his being the registered holder of 100 shares in the Company. By way of remuneration for their services the Directors shall be paid a yearly sum of £250, to be divided as the Directors may determine.

CITY NOTES.

West Coast of America Telegraph Company.—The receipts of the West Coast of America Telegraph Company for August amounted to £5,450.

Brazilian Submarine Telegraph Company.—The traffic receipts of the Brazilian Submarine Telegraph Company, Limited, for the week ended August 21 amounted to £4,805.

Eastern Telegraph Company.—The Eastern Telegraph Company's traffic receipts for the month of August amounted to £43,703, and to £43,609 in the corresponding period of 1887.

Direct Spanish Telegraph Company.—The traffic receipts of the Direct Spanish Telegraph Company for the month of August amounted to £1,643, against £1,614 in the corresponding period of last year, showing an increase of £29.

Western and Brazilian Telegraph Company.—The traffic receipts of the Western and Brazilian Telegraph Company for the past week, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Company, were £3,991.

Eastern Extension, Australasia, and China Telegraph Company.—The traffic receipts of the Eastern Extension, Australasia, and China Telegraph Company for the month of August, 1888, amounted to £38,103, and to £36,274 in the corresponding period of 1887.

West India and Panama Telegraph Company.—The estimated receipts of the West India and Panama Telegraph Company for the half-month ended August 31, 1888, were £2,469, against £2,059 for the corresponding period of 1887. The May receipts, estimated at £5,793, realised £5,830.

PROVISIONAL PATENTS, 1888.

AUGUST 24.

12,198. **Improvements in electrical switches.** Frederick Thomas Schmidt, 27, Highfield-lane, Keighley, Yorkshire.

12,235. **Application of electricity to the lighting of road vehicles.** Francis Hazlett and John Hercules Percival, Gray's Inn Chambers, 20, High Holborn, London, W.C.

AUGUST 25.

12,264. **Improvements in the means of preparing metallic surfaces for the reception of non-adhesive electro deposits.** Francis Edward Elmore and Alexander Stanley Elmore, Armaside, Cockermouth.

12,289. **Improvements in electric propulsion on railways.** Sebastian Ziani de Ferranti, 24, Southampton-buildings, London, W.C.

12,290. **Improvements in galvanic batteries.** Alexander Schanschieff, 24, Southampton-buildings, London, W.C.

12,297. **Switchboard and handles.** Gustav Adolph Abrath, Borough-road, Sunderland, Durham.

Digitized by Google

AUGUST 27.

12,309. **An improved rose for electrical purposes.** Edward William Johnstone, Bow Electric Works, Arnold-road, Bow, E.

12,332. **Improvements in electric meters.** Jules Cauderay, 24, Southampton-buildings, Chancery-lane.

AUGUST 28.

12,376. **Improvements in electric accumulators and in means for their manufacture.** William Lloyd Wise, 46, Lincoln's-inn-fields, London, W.C. (Jean Theodore Van Gestel, United States.)

12,383. **Improvements in electric arc lamps.** Charles Wells, 22, Southampton-buildings, Chancery-lane, W.C., Middlesex.

12,388. **Improvements in and relating to electrical signalling apparatus for domestic and other purposes.** Leslie Watt Winnall and William Howard Winnall, 4, South-street, Finsbury, London.

12,395. **Improvements in electro-therapeutic belts.** Alfred Julius Boult, 323, High Holborn, Middlesex. (Harry P. Pratt, United States.) (Complete specification.)

12,396. **Improvements in electric-motors for self-winding clocks.** William Phillips Thompson, 6, Lord-street, Liverpool. (Daniel W. Edgecomb, United States.) (Complete specification.)

12,409. **Improvements in effecting and controlling the feed of the carbons used in the arc lamps of electric "search lights" or "projectors."** Ronald Augustus Scott, 23, Andalus-road, Clapham, S.W.

AUGUST 29.

12,437. **Improvements in electrical conductors or cables.** William A. Conner and Joseph W. Marsh, 55 and 56, Chancery-lane, Middlesex. (Complete specification.)

12,446. **Improvements in electric telegraphs.** John Julius Ebel, Julia Cottage, Charlton-lane, Charlton, Kent.

12,452. **Improvements in electrical locomotives or traction engines.** Auguste Sandron, 323, High Holborn, Middlesex.

12,453. **Improvements in apparatus for hardening and tempering by electricity.** William Phillips Thompson, 6, Lord-street, Liverpool. (Philip Diehl, United States.) (Complete specification.)

12,455. **Improvements in the application of primary batteries and electro-motors to tricycles and other velocipedes.** John Sherrin and John Vaughan Sherrin, 77, Chancery-lane, London, W.C.

AUGUST 30.

12,505. **Improvements in joints for electric mains.** Sebastian Ziani de Ferranti, 24, Southampton-buildings, London, W.C.

COMPLETE SPECIFICATIONS ACCEPTED.

OCTOBER 14, 1887.

13,960. **A novel combination of spring-jack and lightning arrester for use in or with a test-board for telephone wires and means of carrying, and a method of arranging, any required number of sets or apparatus formed of such combination; such invention being applicable also for the purpose of a telephone switch-board, and for other analogous electrical purposes.** Alfred Coleman and Hubert Feilden Jackson, 169, Fleet-street, London.

OCTOBER 22, 1887.

14,390. **An electric firing fuse or primer.** Richard Morris, 28, Southampton-buildings, Chancery-lane, London, W.C.

OCTOBER 25, 1887.

14,528. **Improvements in microphones.** Charles Bell, 96, Buchanan-street, Glasgow. (Lars Magnus Ericsson, Sweden.)

14,529. **Improvements in microphones.** Charles Bell, 96, Buchanan-street, Glasgow. (Lars Magnus Ericsson, Sweden.)

OCTOBER 28, 1887.

14,658. **Improvements in electric indicators.** George Edwin Fletcher, 93, Chatham-street, Edgeley, Stockport.

MAY 3, 1888.

6614. **Improvements in the electrical illumination of clock dials, and apparatus in connection therewith.** Ernest George Craven, 4, Little Moorfields, E.C.

JUNE 29, 1888.

9501. **An improved screw grip for adjustable lamp and other standards and for electric pendent lamps.** William Arthur Smith Benson, John Lovegrove, and Elie Hinton, trading as W. A. S. Benson and Co., 82, New Bond-street, London, W.

JULY 24, 1888.

10,691. **Improvements in or relating to electrical transmitting instruments.** Alfred Julius Boult, 323, High Holborn, Middlesex. (James Francis McLaughlin, United States.)

SPECIFICATIONS PUBLISHED.

1887.

10,663. **Electrical type-writers, &c.** A. J. Boult (McLaughlin.) 1s. 1d.

10,836. **Electrical firing mechanism for ordnance.** C. A. McEvoy. 8d.

11,928. **Indicating fire damp in coal mines, &c.** J. W. Swan. 8d.

12,880. **Producing solid metal sheets by electro-deposition.** W. J. Reynolds. 6d.

13,709. **Indiarubbor compensators for telegraph, &c., wires.** R. S. Bozon. 8d.

1888.

4659. **Making and breaking electrical circuits in connection with call boxes, &c.** F. T. Schmidt. 8d.

7848. **Indicators for alternating electric currents.** W. P. Thompson. (Westinghouse.) 8d.

7849. **Detecting and locating faults in alternate current electric circuits.** W. P. Thompson. (Westinghouse.) 8d.

7998. **Shades, &c., for incandescent electric lamps.** F. Holman. 8d.

8233. **Cylinder welding apparatus.** S. Pitt. (Rowland and Others.) 6d.

9206. **Galvanic elements.** C. Lutcke and P. George. 8d.

9331. **Relays.** F. Stitzel and C. Weinedel. 8d.

9660. **Electric-motors and dynamo machines.** A. J. Boult. (Lugo.) 1s. 1d.

9661. **Telephone transmitters.** A. J. Boult. (Emmner.) 8d.

NOTES.

Electric Cure.—A Kentucky doctor states that the actinic effect of exposure to the arc light is a cure for yellow fever.

The Garrick Theatre.—The new Garrick Theatre in Charing-cross-road is to be lighted by electricity on the most approved system of theatre lighting.

Harbour Lights.—The German harbour authorities are having some of the various harbour boats fitted with arc lights, for the purpose of illuminating the whole harbour at night.

Notice.—Owing to the number of British Association papers the continuation of the articles on "The Magnetic Field" and "The Young Electrician's Diary" will be held over for the present.

New Fibre.—The discovery is reported of a new fibre for filaments, which gives excellent results. The Companhia Lampada Braziliera has been formed in Rio Janeiro to work the patents.

Indian Telegraph. — Telegraphic communication between India and Europe, *vid* Egypt, has been restored, one of the Bombay-Aden cables of the Eastern Telegraph Company having just been repaired.

Electric Light v. Gas.—The Barnet Gas Company will reduce their price another 3d. per 1,000 feet from the 5th of January, 1889; but the electric light will not be stopped by sops of threepenny-pieces.

Tynemouth.—At the last meeting of the Tynemouth Town Council, it was resolved, by a majority of two to one, that application be made for a provisional order for lighting the borough with the electric light.

Prof. Ayrton's Lecture.—The lecture on "Transmission of Power," by Prof. Ayrton, has proved so interesting that, at the request of several working men, it was given over again on Thursday before a popular audience.

Versailles.—The town of Versailles is to be lighted by electricity by an electric light company having its station at Marly, seven miles away. A high tension current will be brought to Versailles and distributed by means of transformers.

The Telephone in China.—China is coming to the fore with the telephone. The Viceroy of Kouang and the Governor of Canton are having telephones put up between their offices. The Chinese are evidently going to make up for the time lost in the past.

Long Distance Telephony.—Telephonic communication was opened on Tuesday between Berlin and Breslau. The line is the longest in Germany, being 360 kilometres (about 220 miles). Every word was heard most distinctly in Berlin as well as in Breslau.

Fire Alarm Signals.—An electrical flash-light signal has been patented by Mr. William H. Thompson, of Richmond, Va. This invention is designed to provide a simple and efficient visual signalling apparatus for immediate use in cases of fire alarm or for police signals.

House-to-House Supply Company.—We are informed that the directors of this company have accepted the tender of Messrs. Peto Brothers for the erection of their first central electric lighting station at West Brompton. The building will be completed by the month of November.

Bristol.—The contract for the erection of electrical controlling apparatus and signals in connection with the machinery in a new granary built by the Docks' Committee of the Council of the city of Bristol, has been secured by Messrs. King, Mendham and Co., electrical engineers, of that city.

Death of Prof. Edlund.—Prof. Eric Edlund, member of the Royal Academy of Science of Sweden, died at Waxholm, near Stockholm, on the 19th of August last, in his 70th year. The celebrated Swedish professor contributed greatly to the knowledge of modern science in connection with electrical research.

Accumulator Cars.—An electric car, with one hundred storage cells placed under the seats, has been tested in Philadelphia by the Electric Car Company. The car was run 63 miles with one charging, but for ordinary work it is intended to charge every 40 miles run. The weight of motor and cells, &c., is 5,800lb., and the total weight of car 9,200lb.

Submarine Electric Vessel.—A submarine vessel, invented by Lieutenant Peral, of the Spanish Navy, was launched from the La Carraca Arsenal, Cadiz, on September 8. The vessel, which will be completed next month, is cylindrical in shape, and of 87 tons register, and is provided with twin screws, an electric engine, and a torpedo tube.

The B.T. System in Germany.—The small town of Dobhain is supplied with electric light on the battery system. The accumulators used are those of the Tudor type which we described some time since. Overhead wires are used, and the light is supplied for the same price as petroleum, the price being not much over a farthing per lamp an hour.

Castleford.—At the last ordinary meeting of the Castleford Local Board, in consequence of the gas company having positively declined to make any reduction in the price of gas supplied to the Board, it was resolved, on the recommendation of the Finance Committee, that the clerk make inquiries as to the feasibility and cost of providing a substitute for gas.

Strand District.—At the meeting of the Strand District Board of Works, on Wednesday, applications were received from the London Electric Supply Corporation, Limited, and the East Strand and District Electric Light and Power Company, Limited, for a license authorising the supply of electricity within the area of this district, and were referred to the Lighting Committee.

Sometimes Happens.—On the evening of the 30th ult. the whole of the city of Perth was plunged into darkness by the man in charge at the gas works turning off the wrong regulator. Moreover, although he turned it on again at once the light did not return, and the public gas-lighters had to go round again. The discomfort was great that night in Perth, and the smell of gas in the streets was alarming.

Percentage of Telephones.—London, with a population put at 4,765,000, contains only 4,193 subscribers to the telephone, while Stockholm, with a population of only 215,000, has 4,832 subscribers. Out of 12 of the principal cities of Europe, London stands last but two in telephone progress, the average of subscribers here being 0·9 per 1,000, as against 22·5 in Stockholm, 6·4 in Rome, 3·3 in Berlin, and 1·4 in Paris.

Digitized by Google

Electrical Firedamp Indicator.—An automatic electrical firedamp indicator has been devised by M. Molas for the purpose of warning both the men in the mine and the engineers at pit's mouth. It is merely a system of electrical contact actuated by the upward pressure of the escaping gases. When these contacts are made bells are rung, and indicators lowered at the surface, and warning lamps are lit in the mine itself.

Paris-Marseilles Telephone.—This line has been open to the public since August 6. The method of procedure is as follows: The first half-hour in every hour is devoted to through communications from Paris to Marseilles; in the second half-hour Lyons and Paris are connected on one part of the line, and Lyons and Marseilles on the other. This method of alternate connection is kept up all day from seven in the morning till nine at night.

Six Thousand Telegraph Clerks Ready to Strike. According to the *Daily News* correspondent, great discontent is shown in Paris at the way in which promotion in the telegraph service is made. A meeting of over 500 telegraph clerks was held last Tuesday, and it was stated that 6,000 were ready to join them; a committee was formed to create a fund, and to enter into relations with the whole service, and was empowered to draw up a petition to the Postmaster-General.

Treatment of Copper Ore by Electricity in Spain.—M. Escozura, chief engineer of the Department of Mines in Spain, has invented a simple method of treatment of copper ore, by the electrolysis of a solution of sulphate of copper. By this means the production of pure copper is rendered extremely easy; 78 per cent. of the copper contained in the ore is recovered, and the price is very considerably reduced. The process is to be adopted in the Rio Tinto and Lagunazo mines.

A Sliding Scale for Gas.—The Sunderland Gas Company has adopted a somewhat amusing tariff, as under: For small consumers, 1s. 11d.; for consumers of 50,000 cubic feet, 1s. 10d.; above 300,000 cubic feet, 1s. 8d.; while *for those who might be thinking of lighting their places with electricity* the price would be 1s. 6d. nett only. They believed that, with these prices in operation, they would defy comparison with any gas concern in the country. We should imagine they were unique in all respects.

The Telpher System.—We are glad to see by Prof. Ayrton's paper that the telpher system is extending, and is also to be adopted in the Cornish mines. It has always appeared to us that in this system would be found a very good field of activity for enterprising engineers both in mining and in agriculture. There is a regular chain of progression in agriculture—from the spade to the barrow and from the barrow to the cart, but from the cart to the railway is too wide a jump. This hiatus it will be the place of the automatic electric railway to fill.

The Canary Islands.—The Spanish Government are now expending several hundred thousand pounds in improving their Canary Island possessions. The scheme includes the establishment of a line of mail and passenger steamers to run between the seven islands which form the group. The trial trip of the second steamer of the new line—the "Viera-y-Clavijo"—has just taken place on the Clyde. The "Viera-y-Clavijo" is a fine steel screw steamer of 620 tons. She is fitted in a most elaborate style for 150 passengers—first, second, and third class—and is fitted throughout with the electric light.

Electrical Treatment of Sewage.—Mr. Webster states that 25 h.p. will be required to treat one million gallons of sewage per day, with one grain of iron per gallon, representing probably for iron some six or eight shillings per million gallons. If the outfall of the weir or other water power could be utilised for the production of the electricity, a very great saving both in cost and in effectiveness of sewage treatment might be looked for. Municipalities who are at present debating sewage schemes are naturally anxious to know whether this process will be proved to be successful practically.

Colliery Lamps to be "Bonneted."—Mr. A. H. Stokes, F.G.S., H.M. Inspector of Mines for Derby, at the first annual meeting of the National Association of Colliery Managers held at Derby last week, said that it was generally understood that the lamp of the future would be a "bonneted" lamp, and he would suggest to them that once having settled their type they should let every part be made interchangeable. The last suggestion for those who make colliery lamps is admirable, whichever type survives; but we have great faith that the colliery lamp of the future will be an "electric" one rather than a "bonneted."

City Commission of Sewers.—At a meeting of the City Commissioners of Sewers, held at the Guildhall on Wednesday, an application was received from the East Strand and District Electric Light and Power Company for the Commissioners' consent to the application they are about to make to the Board of Trade for a provisional order, or license, to supply electricity in the portion of the City from Farringdon-street and New Bridge-street westward. This was referred to a committee, as was also an application from the London Electric Supply Corporation, for the Commissioners' consent to a licence being granted to them by the Board of Trade for the supply of electricity within the City.

Small Motors.—The advantage of a small and cheap engine always at hand is very apparent for many purposes, and the money-saving or money-producing power of small electro-motors must commend themselves to a great number of trading people as an additional reason for advocating the introduction of an electric circuit into their town. We should like to ask, Are our English manufac turers ready with a small, efficient, and neat-looking motor, suitable for sewing-machines, ventilating fans for rooms, coffee-grinding, knife-polishing, and organ-blowing? as, if not, we shall probably see our wants supplied, when central stations become more general, not by English, but by German or American firms.

Initials by Telephone.—All people who have occasion to telephone names have had great difficulty in making initials understood. B, C, D, E, G, P, T, and V sound so much alike that to distinguish between them is almost impossible, and M and N also sound very similar. A system used in a New Haven newspaper office for some time past, and with very satisfactory results, when the person at the other end of the wire has understood it, is to give a word beginning with the letter that is the initial in question. For instance, suppose the name is B. P. Smith. A score or more of other combinations have almost the same sound, but if the sender says "B. P. Smith; B for butter and P for pepper; B. P. Smith," there is no difficulty in understanding.

Overhead Travellers.—The applications of electric traction are pushing their way into commercial usefulness,

Digitized by Google

and among these small railways for the disposal of heavy goods is an important one. Several applications of electric motors to trucks have been mentioned in conjunction with the ramification of a small electric railway throughout the grounds and buildings. In some cases where work of this kind has to be designed it may be useful to employ overhead rails constructed of iron girders, as a great saving of floor space is thus effected. A system of overhead travellers, with shunts and turntables constructed of iron girders, for use with the ordinary pulling gear, has been introduced by Messrs. Arnold, Goodwin and Son, of 56, Sumner-street, Southwark, and the same method might be advantageously employed when combined with electric motors for moving heavy goods.

The London Electric Supply Corporation.—The London Electric Supply Corporation are about to remove immediately to new and commodious offices at No. 3, Adelphi-terrace, Strand, their present offices at No. 79, Grosvenor-street being no longer sufficiently large for their rapidly-increasing business. The new central generating station of the corporation at Deptford is rapidly approaching completion, and it is understood that the directors will be able to furnish a largely-increased supply of the electric current before the close of the year. The factory and supply station together are some five acres in extent, and we understand the capital idea is to be carried out of imitating the example of the telegraph and carrying the leads into London along the railways. The supply is for 500,000 extra lights. The whole of the work is being carried out under the superintendence of Mr. Ferranti.

Municipal Manufacture of Electric Meters.—A good deal of comment has been made in the French technical papers with regard to the notice recently issued by the Municipal Council of Paris, respecting the prizes for electric meters which it has proposed to offer. It may be remembered that in this notice it is stated that "the city of Paris will reserve the right of manufacture of the prize meters without payment of further royalty." The happy receivers of the prize of £80 may perhaps, it is well suggested, not feel themselves so fully compensated by such a reward as to forego the profits of their invention, and enquiries are further made as to whether, if the "City of Paris" intends to add the manufacture of electric meters to its official duties, it may not also presently take to manufacturing dynamos, steam-engines, and other apparatus—a happy state of affairs for electric light *concessionaires* in Paris!

Electric Sugar.—The *Financial News* this week has a little boom of its own over Prof. Henry Friend's secret process of producing sugar. The shares of the Electric Sugar Company, it seems, have been ignored by the Stock Exchange, but the extraordinary rise from 21 to 104, we are told, has caused the wildest excitement in Liverpool. The *Financial News* publishes special cablegrams of the report of the experiments, similar to what we remember to have read several times before, and "without precautions against deception." It is fair to state that numerous persons have avowed themselves satisfied, and it is said that a plant is to be established capable of turning out 40 tons per hour of refined sugar, at a profit of £4 per ton, and with no waste in syrup. In the absence of details of the process, however, we must prefer to remain sceptical for the time, and shall soon enough be enlightened when we hear of a shipment of some of the "40 tons per hour" of best sugar arriving in Liverpool.

North Shields.—At a quarterly meeting of the Tynemouth Town Council, held at North Shields on Friday, Alderman Joseph Green moved that the Council make application for a provisional order for lighting the public buildings and streets of the borough with the electric light. This was the original idea at the time the present installation and electric light appliances were placed in the New Market. The power was there, and it was only economy to utilise it to its fullest extent. An amendment was moved that the question be remitted back to the committee for further consideration. Councillor Eskdale, in seconding the amendment, thought that to rush into reckless expenditure over additional electric light apparatus would not meet with the favour of the ratepayers. He contended that the scheme meant additional apparatus, and if the Council got this order they would not scruple to exceed their power in carrying the scheme to extremes. After a discussion, however, the resolution was carried by ten votes to five.

Proposal to Light Otley.—At the ordinary meeting of the Otley Local Board on Monday night (Mr. S. Arthur Duncan presiding) Mr. Johnson said that a firm of electric engineers had stated that the quantity of water running through Ellar Gill would be ample to supply power for the generation of electric light for the whole of Otley. As the Board had acquired the Ellar Gill property with the intention of converting it into a storage reservoir, and as the Local Government Board's inspector had condemned the site as unsuitable, it had been described as a "white elephant." Although it had been advertised, there seemed little likelihood of the Board letting the property to pay, and he thought if it could be utilised in the way suggested that would be the best plan to adopt, especially as it was said the town would be greatly benefited by the adoption of the electric light. The chairman said he was perfectly willing for the Board's property to be put to any useful purpose, and though he did not expect that the Ellar Gill would become a mine of wealth in affording electric light, he had no objection to inquiring into the practicability of the proposal. After further discussion, a sub-committee was appointed to obtain information on the subject, and to report to the Board at its next meeting.

Maritime Telegraphing.—M. A. Banaré has communicated to the French Academy of Sciences the result of some experiments in submarine telephony he has undertaken in the harbour of Brest, by order of the Minister of Marine, on August 2 to 13, with the aid of an apparatus he has named the "hydrophone." In these experiments the sounds produced under water by means of various sounding instruments, bell, whistle, or trumpet, have been able to be transmitted under the water; those of a bell weighing 300lb. were easily perceived at all distances allowed by the conformation of the harbour, so as to avoid sandbanks or promontories between apparatus and the point of emission of the signals. The greatest of these distances was 5,200 metres (3½ miles), and the sounds were quite clear and distinct. An official commission was appointed to test the action of the submarine apparatus as compared with the direct sound of a whistle with a moving steamer with very good results, the submarine signals being heard beyond the latter to a distance of one mile. The sound of the bell was always heard with great clearness, in spite of the noise of the machinery and of the screw. Details of the apparatus are not given, and it is not clear, although M. Banaré uses the word telephony, whether the apparatus used is an electric telephone. The field of enquiry is, however, a profitable one, and we are

Digitized by Google

glad to see responsible persons taking the matter up seriously.

Conversazione at All Saints' Works, Derby.—On Friday evening last Messrs. John Davis and Son, the well-known manufacturers of mining apparatus, of All Saints' Works, Derby, entertained the National Association of Colliery Managers (who were holding their first annual meeting in that town) at a conversazione at the new and commodious premises lately erected by the firm, mainly, we believe, in connection with the large development of their electric lighting business. For the purposes of the conversazione, the premises had been extemporised into a delightful combination of an exhibition of scientific apparatus with the lighter pleasures of a social gathering. The broad staircase was carpeted with crimson cloth and tastefully adorned with choice plants and flowers, as, indeed, were the premises throughout. A brilliant programme of music was arranged and choice refreshment *ad libitum* was supplied, under the shade of palms and hot-house ferns, for the mental and physical delectation of the members of the association. The whole of the premises were magnificently lighted with the electric light, and exhibits were shown comprising the very complete electric lighting apparatus of the firm, which included a large arc (the size to be used for street lighting) of 1,000 c.p.; a "Castle" arc lamp, of 500 c.p., suitable for smaller area; a "Sunbeam" incandescent lamp of 150 c.p.; and a number of incandescent lights of the usual 16 c.p. The dynamo used was that known as the "Castle," of 70-light capacity. The results were entirely satisfactory. Messrs. Davis may be congratulated as being the first to satisfactorily demonstrate the excellence and adaptability of the electric light in Derby.

Berlin.—The following description is given by the Berlin correspondent of *Industries*, of the installation of arc lamps in Unter-den-Linden, Berlin. The street contains a promenade of 18yds. width in the centre, a way for heavy traffic on one side, and an avenue for riders on the other. On either side of these are carriageways for light traffic, and finally the footways. The total width of the street between the house fronts is about 190ft. As there are four avenues of trees dividing the five ways, it was not feasible to light the whole of the space effectively from the two sides, and the lamps have, therefore, been arranged in three rows. Altogether, there have been erected 116 lamps, distributed over a distance of about a mile and a quarter. The side lamps are suspended from handsome iron standards with curved tops, and the centre lamps over the promenade from chains stretched between iron posts on either side, so as to leave the whole width of the promenade unobstructed by poles. In order to prevent the suspended lamps from swaying in the wind, the suspending chains are stiffened by diagonal wrought-iron stays attached to the posts. The base of the lamp-post is attached by bolts to a foundation-plate placed 5ft. under the level of the pavement, and the counterweight for the lamp slides up and down within the post. Current is supplied to the lamps by flexible cables carried half-way up the posts, and then passing outside up to the lamps, and a switch is placed in each lamp-post. The lamps are lowered in the usual way for trimming, but when drawn up they rest tightly against an upper casing and reflector of german silver, so as to prevent their swaying about. The globes are of opal glass.

The International Tramway Congress.—At the International Tramway Congress, held at Brussels on September 8, the question of electric traction was brought forward by M. Michelet, the chairman of the Brussels Tramway Company, who gave his experience with the accumulator system, and explained its use on the Brussels tramways. At the beginning the faulty dimensions of the accumulators caused their speedy deterioration. The plates have been made larger and less heavy, and instead of lead, as in the beginning, they are made now of an alloy of lead, antimony, and mercury. The Brussels Tramway Company watches carefully the expenditure for this service. Each battery of accumulators has a special account, to which 10 centimes for every kilometre which has been run is allowed, and a comparison of the results of these accounts is regularly made. A car runs from 100 to 110 kilometres a day. One year at least of the keeping of these accounts, also monthly inventories, are required to determine the cost of the service. M. Michelet considered it safe to predict that very important improvements will be made shortly, his company having received offers from various inventors. For the moment, however, notwithstanding the savings which have been realised in the installation of the dynamos, in the transmission and working expenses, traction by electricity on the Brussels lines continues to be more expensive than animal traction. The afternoon was devoted to a visit to the installations for electrical traction of the Brussels Tramway Company, the examination of the steam-cars (system Rowan) in use on the line Brussels-Schepdael, which belongs to the National Company of Vicinal Railways, and to an excursion to Schepdael. The International Tramway Congress decided to hold its next meeting at Milan in September next year.

"Electric Tramway Systems" Terminology.—A short time since we gave in our columns the report of Mr. Kapp upon the Lineff Tramway System. The criticism of our excellent contemporary, the *Electrical Review*, in its issue of September 7 upon this report, leads us to ask if some common ground cannot be found whereby to designate the proposed or experimental schemes of inventors, patentees, and promoters. Mr. Kapp is called to task because he styles Mr. Lineff's work the "Lineff System." We cannot see the objection to such a term, nor do we think that "arrangement" is to be preferred. In what does an "arrangement" differ from a "system," and how are we to distinguish the one from the other. It may be that the "arrangement" or "system" proposed does not commend itself to the critics, but, for goodness sake, do not let us begin to split hairs in such a fashion as this. We suppose that Mr. Kapp, as an electrical engineer of repute, was employed in the ordinary way to make a report. So far as we know, neither Mr. Kapp nor Mr. Lineff were cognisant of our having a copy of this report, or with our intention of publishing it; therefore we are, in a measure, answerable for having paved the way for these critical remarks. With the opinions as to the value of the system we have nothing to do, except that we cannot undertake to agree to all the conclusions of our contemporary, and especially as to the absolute similarity between Profs. Ayrton and Perry's "arrangement," "scheme," "design," "system," "combination," or whatever word we use to designate it, and that of Mr. Lineff. It might, however, be again pointed out that Mr. Kapp's estimates were based upon figures obtained by a dual trial. The desire to push ahead in electric traction is so universal among engineers, that favourable and unfavourable criticism should be welcomed, as all tends to bring us towards a starting point of agreement.

ELECTRIC DOG-CART FOR THE SULTAN OF TURKEY.

Messrs. Immisch and Co. have had for some little time a mysterious piece of work in hand, the nature of which was known to the initiated as being an electric dog-cart to be constructed to the order of H.M. the Sultan of Turkey. On Wednesday last a number of persons were invited to inspect this automatic vehicle, now completed, and to personally test its running in the Camden Skating Rink, Camden-road.

The appearance of the electric dog-cart is shown by the accompanying illustration. In appearance it is similar to an ordinary four-wheeled dog-cart, but without the shafts. In use the running is very easy and perfectly under control, but it must be said the absence of shafts and a horse gives it at first to the mind of the onlooker a curious, imperfect appearance, comparable to seeing a fowl running about without its head; this effect, no doubt, wears off, but it will be probable, if electric dog-carts come much into use, that a special form of carriage adapted to the needs of accumulators instead of horses will evolve, as the Pullman car has superseded the early railway imitation of the stage coach.

The origin of the idea of the electric dog-cart is due to Mr. Magnus Volk, of Brighton, who constructed an electric dog cart some years ago, and it was the sight or fame of this vehicle that induced the Sultan to give an order for one for his own private use. This order has been entrusted to Messrs. Immisch, in conjunction with Mr. Volk, who have taken advantage of the experience gained with the previous vehicle, and have added several improvements, so that they now believe there is nothing more to be done in the way of making its running a complete success. The dog-cart is constructed with a walnut body and white wood spokes, brightly varnished, and the cushions and hangings are of a harmonious brown colour, and are embroidered with the Turkish Imperial crest—the star and crescent; it is beautifully finished, but, although destined for an Oriental Court, has not been designed to have any specially luxurious appearance.

The motive power is supplied by a set of 24 small E.P.S. accumulators, placed in the body of the cart, of sufficient storage capacity to drive the dog-cart for five hours at the speed of 10 miles an hour. The weight of the accumulators is 7cwt., and that of the carriage, all complete, is 11½cwt.

The motor is Messrs. Immisch and Co.'s 1 h.p. type, using in this case a current of 20 to 25 amperes, with an E.M.F. of 48 volts. When the vehicle is running at a speed of 10 miles an hour, the motor makes 1,440 revolutions per minute, and develops ¾ actual h.p. The motor is connected to one of the wheels by means of a chain, as shown, gearing into a sprocket wheel on the motor shaft. The ratio of gearing of motor to driving wheel is about 18 to 1; the circumference of the wheel being 10ft. 9in. On an ordinary road the amount of work required, of course, varies with the uphill or downhill gradient, and the total amount of work done is thus, on an average, about the same as on level road. The current required to start is about 25 amperes, and for very heavy gradients as much as 45 or 50 amperes could be taken for a few minutes without harm. The motor has been tested up to 90 amperes.

The dog-cart carries four persons; it is started, stopped, and guided without any difficulty by means of a switch with three resistances, and a steering gear fitted to the fore-carriage, with a handle for the driver. The cost is

Electric Dog-Cart made by Messrs. Immisch for the Sultan of Turkey.

Digitized by Google

£200. Rather a rattling noise is made by the commutators and sprocket wheels, but this is said to be not noticeable on ordinary road above the noise of the wheels. One improvement we should suggest before sending away, and that is, that a small actual make-and-break connection should be inserted in the circuit in some safe place under a catch to act as a safeguard, which could be disconnected when the cart is not in use; otherwise the Sultan's ostler might have the astonishing spectacle (if he happened to give the switch-handle an unexpected knock) of seeing the electric dog-cart spin off on a tour by itself, running down several Mussulmen, knocking them over, and drenching them with battery solution.

The experiments made on Wednesday were very successful, many persons enjoying a ride, and the vehicle was under the complete control of Mr. Volk. Messrs. Immisch may be complemented on having produced a really serviceable electric carriage, not merely a king's toy; and we shall expect to see very important developments in commercial usefulness result from their continued work upon the Sultan's electric dog-cart.

THE BRITISH ASSOCIATION.

ADDRESS TO THE MECHANICAL SCIENCE SECTION BY WILLIAM HENRY PREECE, F.R.S., M.I.C.E., ETC., PRESIDENT OF THE SECTION.

(Concluded from page 199.)

In our Central Savings Bank in London it has been found, after two years' experience of electric lighting, that the average amount of absences from illness has been diminished by about two days a year for each person on the staff. This is equivalent to a gain to the service of the time of about eight clerks in that department alone. Taking the cost at the "overtime" rate only, this would mean a saving in salaries of about £640 a year. The cost of the installation of the electric light was £3,349, and the annual cost of working £700 per annum, say a total annual cost of £1,034. The cost of the gas consumed for lighting purposes was about £700 a year, so that on the whole there was a direct saving of something like £266 a year to the Government, besides the material advantage of the better work of the staff resulting from the improved atmospheric conditions under which their work is done.

The production of light by any means implies the consumption of energy, and this can be measured in *watts*, or the rate at which this energy is consumed. A watt is $\frac{1}{746}$ part of a *horse-power*. It is a very convenient and sensible unit of power, and will, in time, replace the meaningless horse-power.

One candle-light maintained by	tallow	absorbs	124	watts.

,, ,,	cannel gas	,,	48	,,
,, ,,	electricity (glow)	,,	3	,,
,, ,,	electricity (arc)	,,	0·5	,,

The relative heat generation of these illuminants may be estimated from these figures.

Though the electric light was discovered by Davy in 1810, it was not until 1844 that it was introduced into our scientific laboratories by Foucault; it was not until 1878 that Jablochkoff and Brush showed how to light up our streets effectually and practically; it was not until 1881 that Edison and Swan showed how our homes could be illuminated softly and perfectly. Unpreparedness for such a revolution produced a perfect panic among gas proprietors; inexperience in the use of powerful electric currents resulted in frequent failure and danger; speculation in financial bubbles transferred much gold from the pockets of the weak to the coffers of the unscrupulous; hasty legislation in 1882 restricted the operations of the cautious and the wise; and the prejudice arising from all these causes has, perhaps fortunately, delayed the general introduction of electricity; but now legislation has been improved, experience has been gained, confidence is being restored, and in this beautiful town of Bath fifty streets are about to be lighted, and we see everywhere around and about us in our English homes the pure glow lamp replacing filthy gas and stinking oil. The economical distribution of the electric current over large areas is annually receiving a fresh impetus. The expensive systems defined in the Act of Parliament of 1882 have entirely disappeared. Hopkinson in England and Edison in America showed how a third wire reduced the weight of copper needed by 66 per cent. Gaulard and Gibbs in 1882 showed how the conversion of alternate currents of high E.M.F. to currents of low E.M.F. by simple induction coils would enable a mere telegraph wire to convey sufficient electricity to light a distant neighbourhood economically and efficiently. Lane Fox, in 1879, showed how the same thing could be done by secondary batteries; and Planté, Faure, Sellon, and Parker have done much to prove how batteries can be made to solve the problem of storage, while King and Edmunds have shown how the distribution by secondary batteries can be done as economically as by secondary generators. The Grosvenor Gallery Company in London have proved the practicability of the secondary generator principle by nightly supplying 24,000 glow-lamps scattered over a very wide area of London. The glow-lamp of Edison, which in 1881 required 5 watts per candle, has been so far improved that it now consumes but 2½ watts per candle. The dynamo, which in the same year weighed 50,000lb., absorbed about 150 h.p., and cost £4,000 for 1,000 lamps, now weighs 14,000lb., absorbs 110 h.p., and costs £500 for the same production of external energy—in other words, its commercial output has been increased nearly six times, while its prime cost has been diminished eight times.

The steam-engine has received equal attention. The economy of the electric light when steam is used depends almost entirely on the consumption of coal. With slow-speed, low-pressure engines, one kilo-watt (1,000 watts, 1⅓ h.p.) may consume 12lb. of coal per hour; in high-speed, high-pressure triple-expansion engines, it need not consume more than 1lb. of coal per hour. Willans and Robinson have actually delivered from a dynamo one kilo-watt by the consumption of 2lb. of coal per hour, or by the condensation of 20lb. of steam.

There is a great tendency to use small economical direct-acting engines in place of large expensive engines, which waste power in countershafting and belts. Between the energy developed in the furnace in the form of heat, and that distributed in our rooms in the form of light, there have been too many points of waste in the intermediate operations. These have now been eliminated or reduced. Electricity can now be produced by steam at 3d. per kilo-watt per hour. The kilo-watt hour is the Board of Trade unit as defined by the Act of 1882, for which the consumer of electric energy has to pay. Its production by gas-engines costs 6d. per kilo-watt hour, while by primary batteries it costs 3s. per kilo-watt hour. The Grosvenor Gallery Company supply currents at 7½d. per kilo-watt hour; a 20 c.p. lamp, consuming 3 watts per candle, and burning 1,200 hours per annum, expends 82,000 watt hours, or 82 kilo-watt hours, and it costs, at 7½d. per unit, 50s. per annum. If the electricity be produced on the premises, as is the case in the post office in the House of Commons, and in many large places, it would cost 20s. 6d. per annum. I have found from a general average under the same circumstances and for the same light in the General Post Office in London, that an electric glow-lamp costs 22s. and a gas-lamp 18s. per annum. The actual cost of the production of one candle light per annum of 1,000 hours is as follows:—

	s.	d.
Sperm candles	8	6
Gas (London)	1	3
Oil (petroleum)	0	8
Electricity, glow	0	9
,, arc	0	1½

The greatest development of the electric light has taken place on board ship. Our Admiralty have been foremost in this work. All our warships are gradually receiving their equipment. Our ocean going passenger ships are also now so illumined, and, perhaps, it is here that the comfort, security, and true blessedness of the electric light is experienced.

Digitized by Google

Railway trains are also being rapidly fitted up. The express trains to Brighton have for a long time been so lighted, and now several northern railways, notably the Midland, are following suit. Our rocky coasts and prominent landmarks are also having their lighthouses fitted with brilliant arc lamps, the last being St. Katherine's Point on the Isle of Wight, where 60,000 candles throw their bright beams over the English Channel, causing many an anxious mariner to proceed on his way rejoicing.

Fontaine showed in Vienna, in 1873, that a dynamo was reversible—that is, if rotated by the energy of a moving machine, it would produce electric currents; or, if rotated by electric currents, it would move machinery. An electric current is one form of energy. If we have at one place the energy of falling water, we can, by means of a turbine and a dynamo, convert a certain portion of the energy of this falling water into an electric current. We transmit this current through proper conductors to any other place we like, and we can again, by means of a motor, convert the energy of the current into mechanical energy to do work by moving machinery, drawing tramcars, or in any other way. We can in this way transmit and utilise 50 per cent. of the energy of the falling water wherever we like. The waste forces of Nature are thus within our reach. The waterfalls of Wales may be utilised in London; the torrents of the Highlands may work the tramways of Edinburgh; the wasted horse-power of Niagara may light up New York. The falls of Bushmills actually do work the tramway from Portrush to the Giant's Causeway, and those of Bessbrook the line from Newry to Bessbrook.

The practicability of the transmission of energy by currents is assured, and the economy of doing this is a mere matter of calculation. It is a question of the relative cost of the transmission of fuel in bulk, or of the transmission of energy by wire. Coal can be delivered in London for 12s. per ton. The mere cost of the upkeep of a wire between Wales and London to deliver the same amount of energy would exceed this sum tenfold. For long distances the transmission of energy is at present out of the question. There can be no doubt, however, that for many purposes within limited areas the transmission of energy by electricity would be very economical and effective. Pumps are worked in the mines of the Forest of Dean, cranes are moved in the works of Easton and Anderson at Erith, lifts are raised in banks in London, water is pumped up from wells to cisterns in the house of Sir Francis Truscott, near East Grinstead; ventilation is effected, and temperature lowered in colleries; goods, minerals, and fuel can be transmitted by telpherage.

The transmission of power by electricity is thus within the range of practice. It can be distributed during the day by the same mains which supply currents for light by night. Small industries, such as printing, watch-making, tailoring, bootmaking, can be cheaply supplied with power. It is thus brought into direct competition with the distribution of power by steam as in America, or by air-pressure as in Paris, or by high-pressure water as in London; and the relative advantages and economies of each system are simple questions of calculation. When that evil day arrives that our supply of natural fuel ceases, then we may look to electricity to bring to our aid the waste energies of Nature—the heat of the sun, the tidal wave of the ocean, the flowing river, the roaring falls, and the raging storm.

There is a mode of transport which is likely to create a revolution in the method of working tramways. A tramcar carries a set of accumulators which supplies a current to work a motor geared to a pair of wheels of the car. The weight, price, day's work, and life of the accumulator is curiously the same as the weight, price, day's work, and life of horseflesh; but the cost of maintenance, the liability to accident, and the chances of failure are much less. Although very great improvements in batteries have been made, and they are now really practical things, sufficient experience in tramcar working has not yet been obtained to say that we have reached the proper accumulator. Nor have we yet acquired the best motor and mode of gearing; but very active experiments are being carried out in various countries, and nothing can prevent their ultimate success.

The property, which the electric current possesses, of doing work upon the chemical constitution of bodies so as to break up certain liquid compounds into their constituent parts, and marshal these disunited molecules in regular order according to a definite law upon the surfaces of metals in contact with the liquid where the current enters and exists, has led to immense industries in electro-metallurgy and electro-plating. The extent of this industry may be gathered from the fact that there are 172 electro-platers in Sheffield and 99 in Birmingham. The term electro-metallurgy was originally applied to the electro-deposition of a thin layer of one metal on another; but this is now known as electro-plating.

In 1839 Jacobi in St. Petersburg and Spencer in Liverpool laid the foundations of all we know of these interesting arts. Copper was deposited by them so as to obtain exact reproductions of coins, medals, and engraved plates. The first patents in this country and in France were taken out by Messrs. Elkington, of Birmingham, who still occupy the foremost position in the country.

The fine metals, gold and silver, are deposited in thin layers on coarser metals, such as german silver, in immense quantities. Christofle, of Paris, deposits annually six tons of silver upon articles of use and of art, and if the surfaces so electro-plated were spread out continuously they would cover 140 acres.

The whole of the copper plates used in Southampton for the production of our splendid ordnance survey maps are deposited by copper on matrices taken from the original engraved plates, which are thus never injured or worn, are always ready for addition or correction, while the copies may be multiplied at pleasure and renewed at will.

Nickel-plating, by which the readily oxidisable metals like iron are coated with a thin layer of the more durable material nickel, is becoming a great industry; the trappings of harness, the exposed parts of machinery, the fittings of cycles and carriages, and innumerable articles of daily use are being rendered not only more durable but more beautiful.

The electro-deposition of iron, as devised by Jacobi and Klein, in the hands of Prof. Roberts-Austen, F.R.S., is giving very interesting results. The dies for the coins which were struck at our Mint on the occasion of the Jubilee of the Queen were modelled in plaster, reproduced in intaglio by the electro-deposition of copper, and on these copper moulds hard excellent iron in layers of nearly $\frac{1}{10}$th of an inch was deposited.

The exact processes of measurement, which have led to such vast improvement in our telegraphic systems, have scarcely yet penetrated into this field of electrical industry, and little is known at present of the exact relations of current and E.M.F. with respect to surfaces of contact, rate of deposit, and resistance of liquids. Captain Sankey, R.E., of the Ordnance Survey Department, has done some useful work in this direction.

The extraction of metals from their ores by deposition has received wide application in the case of copper. In 1871 Elkington proposed to precipitate copper electrolytically from the fused sulphide of copper and iron known to the copper smelter as "regulus." Thin copper plates were arranged to receive the deposited copper while the foreign metals, including gold and silver, fell to the bottom of the solution, the process being specially applicable, it was supposed, to regulus containing small quantities of the precious metals.

The electrical purification of copper from impure "blister copper" or "blade copper" has also made great progress, and special dynamos are now made which will, with an expenditure of 100 h.p., precipitate 18 tons of copper per week. The impure metal is made to form the anode in a bath of sulphate of copper, the metal being deposited in the pure form on a thin copper cathode.

It was not very long ago considered very economical to absorb ·85 h.p. in depositing one pound of copper per hour, but now the same work can be done with ·3 h.p. Mr. Parker of Wolverhampton, has done good work in this direction, and his dynamos in Messrs. Bolton's works have revolutionised this process of purification.

Both at Swansea and Widnes, immense quantities of copper, in spite of the restrictive operations of the copper syndicate, are being produced by electro-deposition. Copper steam-pipes for boilers are now being built up of great firm-

Digitized by Google

ness, fine texture, and considerable strength by Mr. Elmore, at Cockermouth, by electro-deposition on a rotating mandril in a tank of sulphate of copper. By this process one ton of copper requires only a little more than one ton of coal to raise the requisite steam to complete the operation.

It has been shown that the electrolytic separation of silver from gold by similar methods is perfectly practicable. The value of the material to be dealt with may be gathered from the fact, communicated to the Gold and Silver Commission, now sitting, that nearly 90,000,000 ounces of silver are annually produced, and the greater portion of this amount contains sufficient gold to render refining remunerative. Although the old acid process of "parting" gold and silver remains practically undisturbed, there seems no reason to doubt that in the future electricity will render us good service in this direction as it has already in the purification of copper.

There is not much actual progress to report in the extraction of gold from its ores by electrical agency. The conversion of gold into chloride of gold by the direct, or indirect, action of chlorine is employed on a very large scale in [Grass Valley] California and elsewhere. This fact has led to well-directed efforts to obtain by electrolytic action, chlorine which should attack finely-divided gold suspended (with the crushed ore) in the solution from which the chlorine was generated, the gold, so converted into soluble chloride, then being deposited on a cathode. The process would seem to be hopeful, but is not as yet a serious rival to the ordinary chlorination method.

In the amalgamation of gold ores, much is expected from the possibility of keeping clean, by the aid of hydrogen set free by the electric current, the surfaces of amalgamated plates.

It is well known that the late Sir W. Siemens considered that the electric arc might render good service in the fusion of metals with high melting points, and he actually succeeded in melting 96 ounces of platinum in ten minutes with his electrical furnace. The experiments were interrupted by his untimely death, but in the hands of Messrs. Cowles the electric arc produced by 5,000 amperes and 500 h.p. is being employed on a very large scale for the isolation of aluminium (from corundum), which is immediately alloyed *(in situ)* with copper or iron, in the presence of which it is separated.

The heating power of large currents has been used by Elihu Thomson in the United States, and by Bernardos in Russia, to weld metals, and it is said to weld steel without affecting its hardness. It has even been proposed to weld together in one continuous mass long length of the rails of our railways so as to dispense to a great extent with joints.

The production of chlorine for bleaching and of iodine for pharmaceutical purposes, the economical production of oxygen, are also processes now dependent on the electrolytic effect of the electric current.

It is almost impossible to enumerate the various general purposes to which electricity is applied to minister to our wants, and to add to our comforts. Everyone appreciates the silent efficiency of the trembling electric bell, while all will sooner or later derive comfort from the perennially self-winding electric clock. Correct mean time is distributed throughout the length and breadth of the land by currents derived from Greenwich Observatory. Warehouses and shops are fitted with automatic contact pieces, which, on any undue increase of temperature due to fire, create an alarm in the nearest fire station; and at the corner of most streets a post is found with a face of glass, which on being broken enables the passer-by or the watchful and active policeman to call a fire engine to the exact spot of danger. Our sewers are likely to find in its active chemical agency a power to neutralise offensive gases, and to purify poisonous and dangerous fluids. The germs of disease are attacked and destroyed in their very lairs. The physician and the surgeon trust to it to alleviate pain, to cure disease, to effect organic changes beyond the reach of drugs. The photographer finds in the brilliant rays of the arc lamp a miniature sun which enables him to pursue his lucrative business at night, or during the dark and dismal hours of a black November fog of London.

We learn from the instructive and interesting advertising columns of our newspapers that "electricity is life," and we may perhaps read in the more historical portion of the same paper that by a recent decision of the New York Parliament, "electricity is death." It is proposed to replace hanging by the more painless and sudden application of a powerful electrical charge; but those who have assisted at this hasty legislation would have done well to have assured themselves of the practical efficacy of the proposed process. I have seen the difficulty of killing even a rabbit with the most powerful induction-coil ever made, and I know those who escaped and recovered from the stroke of a lightning discharge.

The fact that the energy of a current of electricity, either when it flashes across an air space, or when it is forced through high resistance, assumes the form of heat of very high temperature, led early to its employment for firing charges of gunpowder; and for many civil, military, and naval purposes it has become an invaluable and essential agent. Wrecks, like that of the "Royal George" at Spithead, were blown up and destroyed; the faces of cliffs and quarries are thrown down; the galleries of mines and tunnels are excavated; obstructions to navigation, like the famous Hell Gate, near New York, have been removed; time guns, to distribute correct time, are fired by currents from Greenwich at 1 p.m. In the operations of war, both for attack and defence, submarine mining has become the most important branch of the profession of a soldier and a sailor. Big guns, whether singly or in broadside, are fired, and torpedoes, when an enemy's ship unwittingly is placed over them, are exploded by currents of electricity.

An immense amount of research has been devoted to design the best form of fuse, and the best form of generator of electricity to use to explode them. Gun tubes for firing consist of a short piece of very fine wire embedded in some easily fusible compound, while the best form of fuse is that known as the Abel fuse, which is composed of a small, compact mass of copper phosphide, copper sulphide, and potassium chlorate. The practice in the use of generators is very various. Some, like the Austrians, lean to the high tension effects of static electricity; others prefer magneto machines; others use the dynamo; while we in England cling with much fondness to the trustworthy battery. Since the electric light has also become such a valuable adjunct to war purposes, it is probable that secondary batteries will become of immense service. The strong inductive effects of atmospheric electricity are a source of great danger. Many accidental explosions of fuses have occurred. An experimental cable with a fuse at one end was laid below low-water mark along the banks of the Thames at Woolwich. The fuse was exploded during a heavy thunderstorm. The knowledge of the causes of a danger is a sure means for the production of its removal, or of its reduction to a minimum. Low-tension fuses and metallic circuits reduce the evils of lightning, but have not removed them. Should war unhappily break out again in Europe, submarine mining will play a very serious part, and, paradoxical as it may appear—as has been suggested by the French ambassador, M. Waddington—its very destructiveness may ultimately prove it to be a powerful element of peace.

It seems incredible that, having utilised this great power of nature to such a wide and general extent, we should be still in a state of mental fog as to the answer to be given to the simple question, What is electricity? The engineer and the physicist are completely at variance on this point. The engineer regards electricity, like heat, light, and sound, as a definite form of energy, something that he can generate and destroy, something that he can play with and utilise, something that he can measure and apply. The physicist—at least, some physicists, for it is difficult to find any two physicists that completely agree with each other—regard electricity as a peculiar form of matter permeating all space as well as all substances together with the luminiferous ether which it permeates like a jelly or a sponge. Conductors, according to this theory, are holes or pipes in this jelly, and electrical generators are pumps that transfer this hypothetical matter from one place to another. Other physicists, following Edlund, regard the ether and electricity as identical, and some, the disciples of Helmholtz, consider it as an integral constituent of nature, each molecule of matter having its own definite charge, which determines its

Digitized by Google

attraction and repulsion. All attempts to revive the Franklinian or material theory of electricity have, however, to be so loaded with assumptions, and so weighted with contradictions, that they completely fail to remove electricity from the region of the mysterious. It is already extremely difficult to conceive the existence of the ether itself as an infinitely thin, highly elastic medium, filling all space, employed only as the vehicle of those undulatory motions that give us light and radiant heat. The material theory of electricity requires us to add to this another incomprehensible medium embedded or entangled in this ether, which is not only a medium for motion, but which is itself moved. The practical man, with his eye and his mind trained by the stern realities of daily experience, on a scale vast compared with that of the little world of the laboratory, revolts from such wild hypotheses, such unnecessary and inconceivable conception, such a travesty of the beautiful simplicity of Nature.

He has a clear conception of electricity as something which has a distinct objective existence, which he can manufacture and sell, and something which the unphilosophic and ordinary member of society can buy and use. The physicist asserts dogmatically: "Electricity may possibly be a form of matter—it is not a form of energy." The engineer says distinctly: "Electricity is a form of energy—it is not a form of matter; it obeys the two great developments of the present generation—the mechanical theory of heat, and the doctrine of the conservation of energy." There must be some cause for this strange difference of views. It is clear that the physicist and the engineer do not apply the term electricity to the same thing. The engineer's electricity is a real form of energy; the speculative philosopher's electricity is a vague subjective unreality, which is only a mere factor of energy, and is not energy itself. This factor, like force, gravity, life, must, at any rate for the present, remain unknowable. It is not known what force is; neither do we know what is matter or gravity. The metaphysician is even doubtful as regards time and space. Our knowledge of these things commences with a definition. The human mind is so unimpressionable, or language is so poor, that writers often cannot agree even on a definition. The definition of energy is capacity for doing work. We practical men are quite content to start from this fiducial line, and to affirm that our electricity is something which has a capacity for doing work; it is a peculiar form of energy. The physicist may speculate as much as he pleases on the other side of this line. He may take the factors of energy, and mentally play with them to his heart's content; but he must not rob the engineer of his term *electricity*. It is a pity that we cannot settle our difference by changing the term. Physicists might leave the term *electricity* to the form of energy, which is an objective reality, and which the ordinary mortal understands; while engineers would be quite content if speculative physicists and enthusiastic mathematicians would call their subjective unreality, their imaginary electrical matter, by some other term. If it be necessary to mentally create some imaginary matter to fulfil the assumptions and abstractions of their mathematical realisations, let them call it *coulombism* or *electron*, and not appropriate the engineer's generic and comprehensive term electricity. The engineer finds the motions of existing matter and of the ether quite sufficient to meet all his requirements, and to account for all those phenomena which are called electrical.

It seems paradoxical to assert that two unrealities can form a reality, or that two subjective ideas can become an objective one; but it must be remembered that in all electrical phenomena that which makes them real and objective is derived from without. The motion that renders an electrical phenomena evident is imparted to it from some other form of energy. The doctrine of the conservation of energy asserts that energy is never destroyed, it is only transformed—work must be done to render it evident. No single electrical effect can be adduced which is not the result of work done, and is not the equivalent of energy absorbed. The engineer's notion of work—something done against resistance; and of power—the rate at which this change of condition is effected—are the keystones to the conception of the character of those great sources of power in Nature whose direction to the uses and convenience of man is the immediate profession of those who generally assemble together in Section G of the British Association to discuss the "practical application of the most important principles of natural philosophy which has, in a considerable degree, realised the anticipations of Bacon and changed the aspect and state of affairs in the whole world."

I cannot pretend to have given a survey of all the practical applications of electricity. I have but briefly indicated the present area covered by the new and rapidly-growing industry. Five million people upon the globe are now dependent on the electric current for their daily bread. Scarcely a week passes without some fresh practical application of its principles, and we seem to be only on the shore of that sea of economy and beneficence which expands with every new discovery of the properties of electricity, and spreads already beyond the mental grasp of any one single worker.

ADDRESS TO THE MATHEMATICAL AND PHYSICAL SECTION BY PROF. G. F. FITZGERALD, M.A., F.R.S., PRESIDENT OF THE SECTION.

The British Association in Bath, and especially we here in Section A, have to deplore a very great loss. We confidently anticipated profit and pleasure from the presence in this chair of one of the leading spirits of English science, Dr. Schuster. We deplore the loss and we deplore the cause of it. It is always sad when want of strength makes the independent dependent, and is doubly sad when a life's work is thereby delayed; and to selfish humanity it is trebly sad when, as in this case, we ourselves are involved in the loss. And our loss is great. Dr. Schuster has been investigating some very important questions. He has been studying electric discharge in gases, and he has been investigating the probably allied question of the variations of terrestrial magnetism. We anticipated his matured pronouncements upon these subjects, and also the advantage of his very wide general information upon physical questions, and the benefit of his judicial mind while presiding here.

As to myself, his substitute, I cannot express how much gratified I feel at the distinguished honour done me in asking me to preside. It has been one of the ambitions of my life to be worthy of it, and I will do my best to deserve your confidence; man can do no more, and upon such a subject "the less said the soonest mended."

I suppose most former occupants of this chair have looked over the addresses of their predecessors to see what sort of a thing was expected from them. I find that very few had the courage to deliver no address. Most have devoted themselves to broad general questions, such as the relation of mathematics to physics, or more generally deductive to inductive science. On the other hand, several have dealt each with his own speciality. On looking back over these addresses my attention was specially arrested by the first two past presidents of this section, whose bodily presence we cannot have here. They were presidents of Section A in consecutive years. In 1874 Provost Jellett occupied this chair, and in 1875 Prof. Balfour Stewart occupied it. Both have gone from us since the last meeting of this association. Each gave a characteristic address. The Provost, with the clearness and brilliancy that distinguished his great intellect, plunged through the deep and broad questions surrounding the mechanism of the universe, and with impassioned earnestness claimed on behalf of science the right to prosecute its investigations until it attains, if it ever does attain, to a mechanical explanation of all things. This intrepid honesty to carry to their utmost the principles of whose truth he was convinced, the utter abhorrence of the shadow of double-dealing with truth, was eminently characteristic of one whom all, but especially we of Trinity College, Dublin, will long miss as a lofty example of the highest intellectual keenness and honesty, and mourn as the truest-hearted friend, full of sympathy and Christian charity. In 1875 Professor Stewart gave us a striking example of the other class of address in a splendid exposition of the subject he did so much to advance, namely, solar physics. He brought together from the two great storehouses of his information and speculation a brilliant store, and displayed them here for the advancement of science. Him, too, all science mourns. Though, from want of personal acquaintance, I am unequal to the task of bringing before you his many abilities and great character, you can each compose a fitting epitaph for this well-known great one of British science. In this connection I am only expressing what we all feel when I say how well-timed was the Royal bounty recently extended to his widow. At the same time the niggardly recognition of science by the public is a disgrace to the enlightenment of the nineteenth century. What chancellor or general with his tens of thousands has done that for his country and mankind that Faraday, Darwin, and Pasteur have done? The "public" now are but the children of those who murdered Socrates, tolerated the persecution of Galileo, and deserted Columbus.

In a presidential address on the borderlands of the known delivered from this chair, the great Clerk-Maxwell spoke of as an undecided question whether electro-magnetic phenomena are due to a direct action at a distance or are due to the action of an intervening medium. The year 1888 will be ever memorable as the year in which this great question has been experimentally decided by Hertz in Germany, and, I hope, by others in England. It has been decided in favour of the hypothesis that these actions take place by means of an intervening medium. Although there is nothing new about the question, and

Digitized by Google

although most workers at it have long been practically satisfied that electro-magnetic actions are due to an intervening medium, I have thought it worth while to try and explain to others who may not have considered the problem what the problem is and how it has been solved. A presidential address such as this is not for specialists; it is for the whole section; and I would not have thought of dealing with this subject only that its immediate consequences reach to all the bounds of physical science.

We are all familiar with this, that when we do not know all about something they are generally a variety of explanations of what we do know. Whether there is anything of which there are in reality a variety of explanations is a deep question which some have connected with the freedom of the will, but which I am not concerned with here. A notable example of the possibility of a variety of explanations for us is recorded in connection with an incident said to have occurred in the neighbouring town of Clifton, where a remarkable meteorological phenomenon, as it appeared to an observing scientist, was explained by others as a bull's-eye lantern in the hands of Mr. Pickwick. Another kind of example is the old explanation of water rising in a pump, that "Nature abhors a vacuum," as compared with the modern one. Nowadays, when we know as little about anything, we say, "It is the property of electricity to attract." This is really little or no advance on the old form, and is merely a way of stating that we know a fact, but not its explanation. There are plenty of cases still where a variety of explanations is possible. For example, we know of no *experimentum crucis* to decide whether the people I see around me are conscious or are only automata. There are other questions which have existed, but which have been experimentally decided. The most celebrated of these are the questions between the caloric and kinetic theories of heat, and between the emission and undulatory theories of light. The classical experiments by which the case has been decided in favour of the kinetic theory of heat and the undulatory theory of light are some of the most important experiments that have ever been performed. When it was shown that heat disappeared whenever work appeared, and *vice versa*, and so the caloric hypothesis was disproved; when it was shown that light was propagated more slowly in a dense medium than in a rare, the sciences of light and heat were revolutionised. Not but that most who studied the subject had given their adhesion to the true theory before it was finally decided in general estimation. In fact, Rumford and Davy's experiments on heat, and Young and Fresnell's experiments on light, had really decided these questions long before the erroneous views were finally abandoned. I hope that science will not be so slow in accepting the results of experiment in respect of electro-magnetism as it was in the case of light and heat, and that no Carnot will throw back science by giving plausible explanations on a wrong hypothesis. Rowland's experiment proving an electro-magnetic action between electric charges depending on their absolute and not relative velocities has already proved the existence of a medium relative to which the motion must take place, but the connection is rather metaphysical and is too indirect to attract general attention. The importance of the striking experiments was that they put the language of the wrong hypothesis out of fashion. Elementary text-books that halted between two opinions, and, after the manner of text-books, leant towards that enunciated in preceding text-books, had all perforce to give prominence to the true theory, and the whole rising generation began their researches from a firm and true standpoint. I anticipate the same results to follow Hertz's experimental demonstration of a medium by which electro-magnetic actions are produced. Text-books which have gradually been invoking lines of force, in some respects to the aid of learners and in others to their bewilderment, will now fearlessly discourse of the stresses in the ether that cause electric and magnetic cause. The younger generation will see clearly in electro-magnetic phenomena the working of the all-pervading ether, and this will give them a firm and true standpoint for further advances.

And now I want to spend a short time in explaining to you how the question has been decided. An illustrative example may make the question itself clearer, and so lead you to understand the answer better. In colloquial language we say that balloons, hot air, &c., rise because they are light. In old times this was stated more explicitly, and therefore much more clearly. It was said that they possessed a quality called "levity." "Levity" was opposed to "heaviness." Heaviness made things tend downwards, levity made things tend upwards. It was a sort of action at a distance. At least it would have required such a hypothesis if it had survived until it was known that heaviness was due to the action of the earth. I expect levity would have been attributed to the direct action of heaven. It was comparatively recently in the history of mankind that the rising of hot air, flames, &c., was attributed to the air. Everybody knew that there was air, but it was not supposed that the upward motion of flames was due to it. We now know that this and the rising of balloons are due to the difference of pressure at different levels in the air. In a similar way we have long known that there is an ether, an all-pervading medium, occupying all known space. Its existence is a necessary consequence of the undulatory theory of light. People who think a little but not much sometimes ask me, "Why do you believe in the ether? What's the good of it?" I ask them, "What becomes of light for the eight minutes after it has left the sun and before it reaches the earth?" When they consider that they observe how necessary the ether is. If light took no time to come from the sun there would be no need of the ether. That it is a vibratory phenomenon, that it is affected by matter it acts through—these could be explained by action at a distance very well. The phenomena of interference would, however, require such complicated and curious laws of action at a distance as practically to put such a hypothesis out of court, or else be purely mathematical expressions for wave propagation. In fact, anything except propagation in time is explicable by action at a distance. It is the same in the case of electro-magnetic actions. There were two hypotheses as to the causes of electro-magnetic actions. One attributed electric attraction to a property of a thing called electricity, to attract at a distance, the other attributed it to a pull exerted by means of the ether, somewhat in the way that air pushes balloons up. We do not know what the structure of the ether is by means of which it can pull, but neither do we know what the structure of a piece of india-rubber is by means of which it can pull, and we might as well ignore the indiarubber, though we know a lot about the laws of its action, because we do not know its structure, as to ignore the ether because we do not know its structure. Anyway, what was wanted was an experiment to decide between the hypothesis of direct action at a distance and of action by means of a medium. At the time that Clerk-Maxwell delivered his address no experiment was known that could decide between the two hypotheses. Specific inductive capacity, the action of intervening matter, the delay in telegraphing, the time propagation of electro-magnetic actions by means of conducting material—these were known, but he knew that they could be explained by means of action at a distance, and had been so explained. Waves in a conductor do not necessarily postulate action through a medium such as the ether. When we are dealing with a conductor and a thing called electricity running over its surface, we are, of course, postulating a medium on or in the conductor, but not outside it, which is the special point at issue. Clerk-Maxwell *believed* that just as the same air that transmits sound is able by differences of pressure—*i.e.*, by means of its energy per unit volume—to move bodies immersed in it, so the same ether that transmits light causes electrified bodies to move by means of its energy per unit volume. He believed this, but there was no experiment known then to decide between this hypothesis and that of direct action at a distance. As I have endeavoured to impress upon you, no *experimentum crucis* between the hypotheses is possible except an experiment proving propagation in time, either directly or indirectly, by an experiment exhibiting phenomena like those of the interference of light. A theorist may speak of propagation of actions in time without talking of a medium. This is all very well in mathematical formulæ, but, as in the case of light, we must consider what becomes of it after it has left the sun and before it reaches the earth, so every hypothesis assuming action in time really postulates a medium whether we talk about it or not. There are some difficulties surrounding the complete interpretation of some of Hertz's experiments. The conditions are complicated, but I confidently expect that they will lead to a decision on most of the outstanding questions on the theory of electro-magnetic action. However, there is no doubt that he has observed the interference of electro-magnetic waves quite analogous to those of light, and that he has proved that electro-magnetic actions are propagated in air with the velocity of light. By a beautiful device Hertz has produced rapidly-alternating currents of such frequency that their wave length is only about two metres. I may pause for a minute to call your attention to what that means. These waves are propagated three hundred thousand kilometres in a second. If they vibrated three hundred thousand times a second the waves would be each a kilometre long. This rate of vibration is much higher than the highest audible note, and yet the waves are much too long to be manageable. We want a vibration about a thousand times as fast again with waves about a metre long. Hertz produced such vibrations, vibrating more than a hundred million times a second. That is, there are as many vibrations in one second as there are seconds—in a day? No, far more. In a week? No; more even than that. The pendulum of a clock ticking seconds would have to vibrate for four months before it would vibrate as often as one of Hertz's vibrators vibrates in one second. And how did he detect the vibrations and their interference? He could not see them; they are much too slow for that; they should go about a million times as fast again to be visible. He could not hear them; they are much too quick for that. If they went a million times more slowly they would be well heard. He made use of the principle of resonance. You all understand how by a succession of well-timed small impulses a large vibration may be set up. It explains many things, from speech to spectrum analysis. It is related that a former Marquis of Waterford used the principle to overturn lamp-posts; his ambition soared above knocker-wrenching. So that it is a principle known to others besides scientific men. Hertz constructed a circuit whose period of vibration for electric currents was the same as that of his generating vibrator, and he was able to see sparks, due to the induced vibration, leaping across a small air-space in this resonant circuit. The well-timed electrical impulses broke down the air-resistance just as those of my Lord of Waterford broke down the lamp-post. The combination of a vibrating generating circuit with a resonant-receiving circuit is one that I spoke of at the meeting of the British Association at Southport as one by which this very question might be studied. At the time I did not see any feasible way of detecting the induced resonance; I did not anticipate that it could produce sparks. By its means, however, Hertz has been able to observe the interference between waves incident on a wall and the reflected waves. He placed his generating vibrator several wave lengths away from a wall, and placed the receiving resonant circuit between the generator and the wall, and in this air-space he was able to observe that at some points there were hardly any induced sparks; but at other and greater distances from his generator they reappeared, to disappear again in regular succession at equal intervals between his generator and the wall. It is exactly the same phenomenon as what are known as Lloyd's bands in optics, which are due to the interference between a direct and a reflected wave. It follows hence that, just as Young's and Fresnell's researches on the interference of light prove the undulatory theory of optics, so Hertz's experiment proves the ethereal theory of electro-magnetism. It is a spendid result. Henceforth, I hope no learner will fail to be impressed with the theory—hypothesis no longer—that electro-magnetic actions are due to a medium pervading all known space, and that it is the same medium as the one by which light is propagated, that non-conductors can, and probably always do, as Prof. Poynting has taught us, transmit electro-magnetic energy. By means of variable currents, energy *is* propagated into space with the velocity of light. The rotation of the earth is being slowly stopped by the diurnal rotation of its

Digitized by Google

magnetic poles. This seems a hopeful direction in which to look for an explanation of the secular precession of terrestrial magnetism. It is quite different from Edlund's curious hypothesis that free space is a perfect conductor. If this were true, there would be a pair of great antipoles outside the air, and terrestrial magnetism would not be much like what it is, and I think the earth would have stopped rotating long ago. With alternating currents we *do* propagate energy through non-conductors. It seems almost as if our future telegraph cables would be pipes. Just as the long sound waves in speaking-tubes go round corners, so these electro-magnetic waves go round corners if they are not too sharp. Prof. Lodge will probably have something to tell us on this point in connection with lightning conductors The silvered glass bars used by surgeons to conduct light are exactly what I am describing. They are a glass, a non-conducting, and therefore transparent, bar surrounded by a conducting, and therefore opaque, silver sheath, and they transmit the rapidly alternating currents we call light. There would not be the same difficulty in utilising the energy of these electro-magnetic waves as in utilising radiant heat. Having all the vibrations of the same period, we might utilise Hertz's resonating circuits, and in any case the second law of thermodynamics would not trouble us when we could practically attain to the absolute zero of these, as compared with heat, long period vibrations.

We seem to be approaching a theory as to the structure of the ether. There are difficulties from diffusion in the simple theory that it is a fluid full of motion, a sort of vortex sponge. There were similar difficulties in the wave theory of light owing to wave propagation round corners, and there is as great a difficulty in the jelly theory of the ether arising from the freedom of motion of matter through it. It may be found that there is diffusion, or it may be found that there are polarised distributions of fluid kinetic energy which are not unstable when the surfaces are fixed ; more than one such is known. Osborne Reynolds has pointed out another, though in my opinion less hopeful, direction in which to look for a theory of the ether. Hard particles are abominations. Perhaps the impenetrability of a vortex would suffice. Oliver Lodge speaks confidently of a sort of chemical union of two opposite kinds of elements forming the ether. The opposite sides of a vortex ring might perchance suit, or maybe the ether, after all, is but an atmosphere of some infra-hydrogen element. These two latter hypotheses may both come to the same thing. Anyway, we are learning daily what sort of properties the ether must have. It must be the means of propagation of light ; it must be the means by which electric and magnetic forces exist; it should explain chemical actions, and, if possible, gravity.

On the vortex-sponge theory of the ether there is no real difficulty by reason of complexity why it should not explain chemical actions. In fact, there is every reason to expect that very much more complex actions would take place at distances comparable with the size of the vortices than at the distances at which we study the simple phenomena of electro-magnetism. Indeed, if vortices can make a small piece of a strong elastic solid we can make watches and build steam-engines and any amount of complex machinery, so that complexity can be no essential difficulty. Similarly, the instantaneous propagation of gravity, if it exists, is not an essential difficulty, for vortices each occupy all space, and they act on one another simultaneously everywhere. The theory that material atoms are simple vortex rings in a perfect liquid otherwise unmoving is insufficient, but with the innumerable possibilities of fluid motion it seems almost impossible but that an explanation of the properties of the universe will be found in this conception. Anything purporting to be an explanation founded on such ideas as "inherent property of matter to attract," or building up big elastic solids out of little ones, is not of the nature of an ultimate explanation at all; it can only be a temporary stopping place. There are metaphysical grounds, too, for reducing matter to motion and potential to kinetic energy.

These ideas are not new, but it is well to enunciate them from time to time, and a presidential address in Section A is a fitting time. Besides all this, it has become the fashion to indulge in quaint cosmical theories, and to dilate upon them before learned societies and in learned journals. I would suggest, as one who has been bogged in this quagmire, that a successor in this chair might well devote himself to a review of the cosmical theories propounded within the last few years. The opportunities for piquant criticism would be splendid.

Returning to the sure ground of experimental research, let us for a moment contemplate what is betokened by this theory that in electro-magnetic engines we are using as our mechanism the ether—the medium that fills all known space. It was a great step in human progress when man learnt to make material machines, when he used the elasticity of his bow and the rigidity of his arrow to provide food and defeat his enemies. It was a great advance when he learnt to use the chemical action of fire; when he learnt to use water to float his boats and air to drive them; when he used artificial selection to provide himself with food and domestic animals. For two hundred years he has made heat his slave to drive his machinery. Fire, water, earth, and air have long been his slaves, but it is only within the last few years that man has won the battle lost by the giants of old, has snatched the thunderbolt from Jove himself and enslaved the all-pervading ether.

CORRESPONDENCE.

"FLATS" ON COMMUTATOR.

To the Editor of The Electrical Engineer.

Sir,—I conclude from the tone of Mr. Wallis's letter in your last issue that he rather questions the soundness of my explanation of the cause of "flats" on commutators. The explanation I gave was not, of course, intended to apply to all cases, but simply to the one in question. I think it quite possible that among the sixty bars of copper, of which the commutator is built up, two might be softer than the rest. Even if they were all of an equal degree of hardness in the first instance, is it not likely that in brazing on the tail-pieces the surfaces of some of the bars might be rendered soft, and thus wear more rapidly than the others? Before trying to explain the cause of the "flat" in this way, I had examined all the armature connections and found them perfect. Mr. Wallis attributes the cause to "a defective connection of those segments to the armature, producing, by the resistance it introduces, a greater difference of potential across that particular section than its share of the total."

Now, I fail to see how the fact of a greater difference of potential being produced across a particular section than its proper share causes the two bars of the commutator corresponding to that section to wear flat. Perhaps Mr. Wallis will enlighten me? I think also that Mr. Wallis confounds the action of a motor with that of a dynamo. In the former, the current flowing produces a difference of potential across each section of the armature directly proportional to its resistance. In the dynamo the reverse is the case; it is the E.M.F. generated by the cutting of magnetic lines of force which produces the current, and therefore, if a defective connection introduces an extra resistance in any coil, I cannot see that the E.M.F. of that coil would be increased. It appears to me (but I am open to correction) that its current would be reduced. Again, is it not the fact that, if the brushes are properly set, the coil passing them is in the position of least activity, and therefore generating no E.M.F. at all?

But what about the defective connections that Mr. Wallis has "invariably found"? May I suggest that these were not *causes*, but *effects*? Effects, perhaps, of the high temperature to which the defective bars had been raised.—Yours, &c.,

Broad Bent.

London, September 11, 1888.

PERMANENT MAGNETS.

To the Editor of The Electrical Engineer.

Sir,—Can any of your readers state the practical *modus operandi* of manufacturing permanent magnets? Certain makers of steel profess to supply metal of the best quality for the purpose.

What is the proper heat to raise the steel before shaping the magnets? What portion of the magnet should be tempered, and to what degree of temper? What is the best system of magnetising?

A reply from one or more of your technical readers will much oblige.—Yours, &c.,

S. Z.

September 12, 1888.

Telephone Recorder.—The following particulars are given of a telephone recorder, invented by Edward C. Paramore, Philadelphia, of the American National Telephone Company, of New York, with the assistance of Mr. Bonta, inventor of the Bonta telephone. The inventors have been working on the device for the past four years, and have at last reached what they consider perfection in its construction. The arrangement is contained in a small box, which is placed in proximity to the telephone and connected by wire. No name has yet been given it. A person is called upon the telephone, and, if not present, the person speaking continues talking, the communication being electrically committed to wax paper within the machine. When the person addressed arrives at the other end of the wire, he notices that a ball has dropped on the apparatus, which indicates that someone has been talking. Going to the telephone he opens the switch, when all that has been said previously by the person at the other end of the line commences to be heard in precisely the same tone of voice and at the same rate of speed. The sheets of paper are 8in. by 11in., and can at any time be placed in the machine and the sound be reproduced.

THE
ELECTRICAL ENGINEER.

Published every Friday.
Price Threepence; Post Free, Threepence Halfpenny.
Editorial and Publishing Offices:
139-140, SALISBURY COURT, FLEET STREET, LONDON, E.C.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering, which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140, Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY, with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had, by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months.	6 months.	12 months.
nited Kingdom.....	3s. 3d. ...	6s. 6d. ...	13s. 0d.
Within the Postal Union	4s. 4d. ...	8s. 8d. ...	17s. 4d.
Other Places.....	4s. 10d. ...	9s. 8d. ...	19s. 6d.

(Post Free, Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscriptions and Advertisements, should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, ESQ., *President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of* W. H. WOLLASTON, M.D., F.R.S., *and on April 20th we gave that of* SIR HUMPHRY DAVY, F.R.S., *whose fame as an electrician is still more prominent than that of* WOLLASTON. *Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of* PROF. D. E. HUGHES, F.R.S.

THE B.A., 1888.

Elsewhere we give a complete list of the electrical papers read at the Bath meeting of the British Association. The full text of the papers or a sufficiently full abstract will in due course be given in our columns, and thus our readers will be able to form their own opinions as to the scientific or practical value of the meeting, and may take to heart the lessons to be learned therefrom. There really does seem some grounds for the jubilation apparent in Section A, which gave rise to an opinion expressed with increasing fervour to the close of the meeting, that the year's proceedings will mark the commencement of an epoch in the history of electrical investigation. Prof. Hertz's experiments, which formed the text of Prof. Fitzgerald's address to the section, supplemented as they were by experiments carried out by Prof. Lodge, have opened out to the mind of the physicist a vision beautiful to contemplate, a new field of research, a field hitherto untrodden, and therefore unexplored. The ear takes cognisance of sound waves, the eye of light waves. The former are comparatively slow, the latter tread upon the other extreme. Between the two lies an unexplored region, and it is into this region that the experiments of Hertz and Lodge take us. Prof. Fitzgerald, at the Southport meeting, hinted at the possibility of exploring this region, and suggested that the electric current might furnish the means. Prof. Lodge, not content with describing his experiments, has ventured to point out the possibilities that environ practical applications in the prosecution of the researches into this new field. It is well known, he pointed out, that ordinarily to obtain those vibrations which produce the sensation of light, a vast number of other vibrations are generated which are not required, and the cost of producing the light waves is enormously increased by having to perform this extra work. He forsees, dimly it may be, the possibility of getting rid of the steam-engine and the dynamo as wasteful, and, with our perfected knowledge, useless accessories in the product of light. A small boy turning a handle is to produce the necessary vibrations. Perhaps, however, the steam-engine will be of some use to replace a few hundreds of these small boys. It will be seen that Prof. Lodge aims to produce light waves only. Of course, if such an idea is ever realised, it will revolutionise our present systems of lighting, though manufacturers need take no alarm, for, even if the proverb that threatened men live long, failed, the business of the manufacturer would remain in the construction of the new forms of apparatus required. It is only the few who can conceive the realisation of these hopes, for the many can only understand that, so far as they are concerned, direct commercially useful transformations are almost unknown. Passing from what may be termed the most important scientific

Digitized by Google

question of the meeting, we should instance as one of the most interesting to practical men the paper of Messrs. Lowrie-Hall-Kolle for the measurement of alternate currents supplied to consumers. These gentlemen propose a system which has been satisfactorily tried at Eastbourne for nine months past. In the converter circuit they place a depositing cell and a secondary battery cell, the latter having practically a constant E.M.F. of two volts. During one-half the period the E.M.F. of the converter circuit acts with that of the accumulator, and during the other half against it. This causes, supposing the E.M.F. of the converter circuit to be 100 volts, a deposition during the half period in the depositing cell from a current under an effective voltage of 102 volts, while the reverse action reducing the deposit is due to a current under a voltage of 98 volts. The deposit therefore is equivalent to a deposit during the whole period of working of a current with E.M.F. of two volts. The deposit due to one hour's working being known, it only remains to divide the weight of the total deposit by this unit, and the number of hours total working is known. The result is—time that the current has been employed. The arrangement is very ingenious, but there are many objections to its use on a large scale. The multiplication of terminals necessary in the connections of the cells is one weak point, the constant supervision of the cells is another, and though one almost blushes to refer to it, yet taking the world as it is, cheating the producer would be rendered an excessively easy affair. Either the depositing cell or accumulator would be short-circuited out of practical existence so far as the time measurement is concerned. But our readers will have an opportunity of reading the paper and deciding for themselves the value of the suggestion for work upon a large scale.

The Bath meeting was not to pass without new suggestions to mechanical and electrical nomenclature. The Committee on Mechanical Nomenclature suggest the use of the terms *Kine*, *Bole*, and *Barad*, thus:—

1 cm. per sec. = 1 kine.
1 gramme kine = 1 bole.
1 dyne per sq. cm. = 1 barad.

The Committee on Electrical Standards, at the request of Mr. Preece, recommend the adoption of the term *Therm* as the amount of heat required to raise one gramme of pure water one degree centigrade at the temperature of maximum density, and *Joule* as the work done by a watt per second.

The uncouthness of some of these terms was put forward as a reason for their adoption, as their unfamiliarity would compel closer attention and lead to their being easily remembered.

We have thus briefly mentioned what we take to be the salient features of the meeting, but there is one other subject to which reference must be made. Some people go to the sections to read, and some to hear papers, others seem to go for no earthly object whatever except it be to move about as noisily as possible at the most inconvenient moments. The clumsy clod-hopper could hardly make more noise in the village "pub." than do some men in moving into or out of the meeting rooms. They are either stupidly ignorant or so intensely conceited that they cannot understand the harm they do. The same remarks apply to the evening meetings. The moment the lecturer has ceased, the hall begins to be somewhat of a bear-garden. No matter the eminence of the mover and seconder of the vote of thanks, no matter how opportune the remarks they have to make, a considerable part of the audience rush for the doors, and render it impossible for those who wish to hear comfortably. If the B.A. is to be looked upon in the light of a picnic, by all means let it be so, but even at a picnic courtesy is not unknown, and it would seem desirable to discuss in Section F some such paper as "Courtesy to speakers at modern meetings."

ELECTRICAL PAPERS AT THE BRITISH ASSOCIATION.

The following is a complete list of the papers on electrical subjects read at the British Association:

Section A.

Prof. F. G. FITZGERALD, M.A., F.R.S.—President's Address.
Prof. W. STROUD and W. W. HALDANE GEE.—"Electro-Calorimetry."
J. BROWN.—"On Figures produced by Electric Action on Photographic Dry Plates."
W. LANT-CARPENTER.—"Comparison of Gassner's Dry Cells with Leclanché's."
A. TANAKADATE.—"On the Magnetisation of Soft Iron Bars of Different Lengths in a Uniform Field."
Report of the Committee on Electrolysis:
(i) Prof. G. F. FITZGERALD, F.R.S., and F. TROUTON.—"Further Examination of Ohm's Law in Electrolytes."
(ii.) Dr. J. H. GLADSTONE, F.R.S., and W. HIBBERT.—"On the Conduction of Alloys and Solid Sulphides."
(iii.) Prof. H. E. ARMSTRONG, F.R.S.—"On the Purification of Selenium."
(iv.) Dr. FRANZ RECHARZ.—"On the E.M.F. of Polarisation with Small Electrodes."
(v.) Dr. ARRHENIUS.—"On Dissociation in Electrolytes."
Lord RAYLEIGH, F.R.S.—"Is the Velocity of Light in an Electrolytic Liquid Influenced by an Electric Current in the Direction of Propagation?"
Prof. OLIVER J. LODGE, F.R.S.—"On the Measurement of Electro-Magnetic Wave-Lengths."
Prof. OLIVER J. LODGE, F.R.S.—"On the Impedance of Conductors to a Leyden Jar Discharge."
Sir W. THOMSON, F.R.S.—"A Simple Hypothesis for Electro-Magnetic Induction of Incomplete Circuits, with Consequent Equations of Electric Motion in Fixed Homogenous or Heterogeneous Solid Matter."
Sir W. THOMSON, F.R.S.—"On the Transference of Electricity within a Solid Conductor."
Sir W. THOMSON, F.R.S.—"Five Applications of Fourier's Law of Diffusion, illustrated by a Diagram of Curves, with absolute numerical values."
Prof. W. M. HICKS, F.R.S.—"A Vortex Analogue of Static Electricity."
Report of the Committee on Magnetic Observations.
Prof. C. G. KNOTT.—"On the Recent Magnetic Survey of Japan."
J. JOLY.—"On Reading Electrically Meteorological Instruments Distant from the Observer."
W. N. SHAW.—"On an Apparatus for Determining the Temperature by the Variation of Electrical Resistance."
Report of the Committee on Standards of Light.
Joint Discussion with Section G on "Lightning Conductors," opened by Mr. W. H. PREECE, F.R.S., and Prof. OLIVER J. LODGE, F.R.S.

R. E. CROMPTON.—"Cowles's Process of Electric Smelting."

G. FORBES.—"Electric Lighting in America."

H. EDMUNDS.—"Edmunds's System of Electrical Distribution."

W. LOWRIE.—"The Measurement of Electricity in a House-to-House Supply."

R. P. SELLON.—"Suez Canal Lighting."

F. BRAIN.—"Electricity as applied to Mining."

N. WATTS.—"Miners' Electric Safety Lamps."

J. W. SWAN.—"An Automatic Fire-Damp Indicator."

ON RECENT DEVELOPMENTS OF THE COWLES' ALUMINIUM PROCESS.*

BY R. E. CROMPTON.

It is unnecessary to again describe the earlier stages of the Brothers Cowles' invention of the electric furnaces. I confine myself to a description of such parts of the new plant which has been recently put down at Milton, near Stoke-on-Trent, that I think will be of general scientific interest.

The experience in America at the works at Lockport, Ohio, showed conclusively that great economies were to be expected from increasing the size of the furnaces and the strength of the electric current employed to work them, but no current larger than 3,000 amperes had been used up to the time that the Milton works were planned.

Mr. Eugene Cowles came over to England to ascertain whether English makers of dynamo machines were prepared to supply one sixty per cent. larger than Mr. Brush's "Colossus," which had been made especially for them in America, and which was then the largest direct current machine in the world. He prepared his specification for a dynamo to give a current of 5,000 amperes at 60 volts, and eventually Messrs. Crompton's design and tender were accepted. The works were built near the Milton station on the North Staffordshire Railway. The boilers for generating the steam required are of the Babcock-Wilcox type, and are provided with mechanical stokers. The steam-engine is of 600 h.p., and is a compound condensing horizontal tandem, made by Messrs. Pollit and Wigzel, of Sowerby Bridge. It is furnished with an exceedingly perfect centrifugal governor, which maintains the speed accurately at seventy-six revolutions in spite of very great fluctuations in the load. The electrical means of stopping the engine have been provided in the shape of Tate's electrical stop valve, which may be described as an electro-magnet arrangement, with the ordinary pushes for completing the circuit, which actuates a steam relay piston set to close the main stop valve. The fly-wheel of this engine is 20ft. in diameter, and weighs 30 tons, and is geared to the pulley of the dynamo, so that the latter makes five revolutions for every revolution of the engine by rope driving gear, consisting of eighteen ropes. This engine is an extremely fine specimen of a modern steam-engine. It works so silently that a visitor standing in the engine-house with his back to the engine railings at the time the engine is being started cannot tell whether it is in motion or not. The dynamo at first sight seems very small when compared with the steam-engine driving it; the fact is that it is dwarfed by the enormous fly-wheel of the engine. It is only when one stands close to the plummer block bearings that one realises the great size of the spindle and of all the parts required to transmit the power to the armature coils. The author was well aware when designing this machine that the mechanical strains on the spindle core attachments and winding were likely to be of an extraordinary nature. The following precautions were, therefore, adopted, and, as events have turned out, these have been more than justified. The spindle is of steel 18ft. long, with three bearings, one being placed on either side of the driving pulley. The diameter is 7in. in the bearings and 10in. in the part within the core. This part in the original forging was 14in. diameter, and was placed longitudinally, so as to leave four projecting ribs or radial bars, on to which the core discs are driven, each disc having four keyways corresponding to these ribs. There are about 900 of these discs, the external diameter being 20in., and the total length of the core 36in. Originally the core was provided with 32 driving teeth made of steel, each tooth riveted to sockets attached to eight of the core discs. It may here be mentioned that, as the working has shown, the strain on these driving teeth was perilously near their factor of safety; their number has been doubled, so that now the tangential strains are borne by a very considerable number of the core discs. The armature winding consists of 128 copper bars, each ¾in. deep, measured radially, by ¾in. wide. These 128 bars are coupled up so as to form 32 conductors only; this arrangement has been adopted to avoid the heating from Foucault currents, which, with 1½in. conductors would have been very considerable. The bars are coupled at the ends of the core across a certain chord according to an arrangement patented by the author and Mr. Swinburne, which consists of crescent-shaped bars so formed that the whole surface is thoroughly exposed to the current of air passing through the armature. They are also somewhat shorter than those usually employed on drum-wound armatures. The bars are insulated by a covering of fiburite, a material which has been recently introduced by Messrs. Crompton, and which will stand a temperature of 160deg. C. for long periods without the least discolouration or alteration of its mechanical or insulating properties. The commutator is 20in. long, has 64 parts, and, in addition to the usual tightening nuts at the two ends, is provided with a third tightening ring at the centre, to prevent the tendency of such long commutator strips to spring when worn down thin. The current is collected by eight brushes, mounted on a separate ring placed concentric to the commutator, and the current is led away from these brushes by a large number of bands of sheet-copper strapped together into convenient groups. The field-magnets are of the horizontal double type, and were adopted by the author and Mr. Swinburne, after a careful series of experiments which convinced them that the fashionable single-magnet form was very unsuitable for this kind of machine. As this machine is virtually a series-wound machine, the magnet-coils each consist of a few turns only of forged-copper bars, 1½in. wide by 1in. thick, forged to fit the magnet-cores. There is no insulation other than thin mica wedges to keep the bars from touching the core. The armature is ventilated by a current of air from a Shieles fan, driven by a belt from the armature spindle. At 380 revolutions the armature can give 5,000 amperes at 60 volts, and the temperature of the hottest part, which is the end-plates next the commutator, never rises beyond 70deg. C. Although this machine was designed to give only 5,000 amperes, yet, electrically speaking it is capable of doing very much more, and in actual practice it has frequently to stand a current of 8,000 amperes for short periods; but, as will be shown later, when the furnaces are employed to produce ferro-aluminium there are frequently violent oscillations in the current which would make it unsafe to employ an average current much in excess of 5,000. In fact, as has been stated above, it has been found necessary already to increase the number of driving teeth in order to provide against the driving strains at the times of maximum current. When the machine was first tried the main circuit was unprovided with a cut-out, and there is no doubt that at this time the armature stood the test more than once of temporary currents exceeding 16,000 amperes. Since that time a safety cut-out has been provided calculated to fuse at 8,000 amperes. This—probably the largest one that has ever been designed—consists of a framework carrying twelve lead plates, and these fuse at the calculated point in a most satisfactory manner without any undue detonation or scattering of the molten lead.

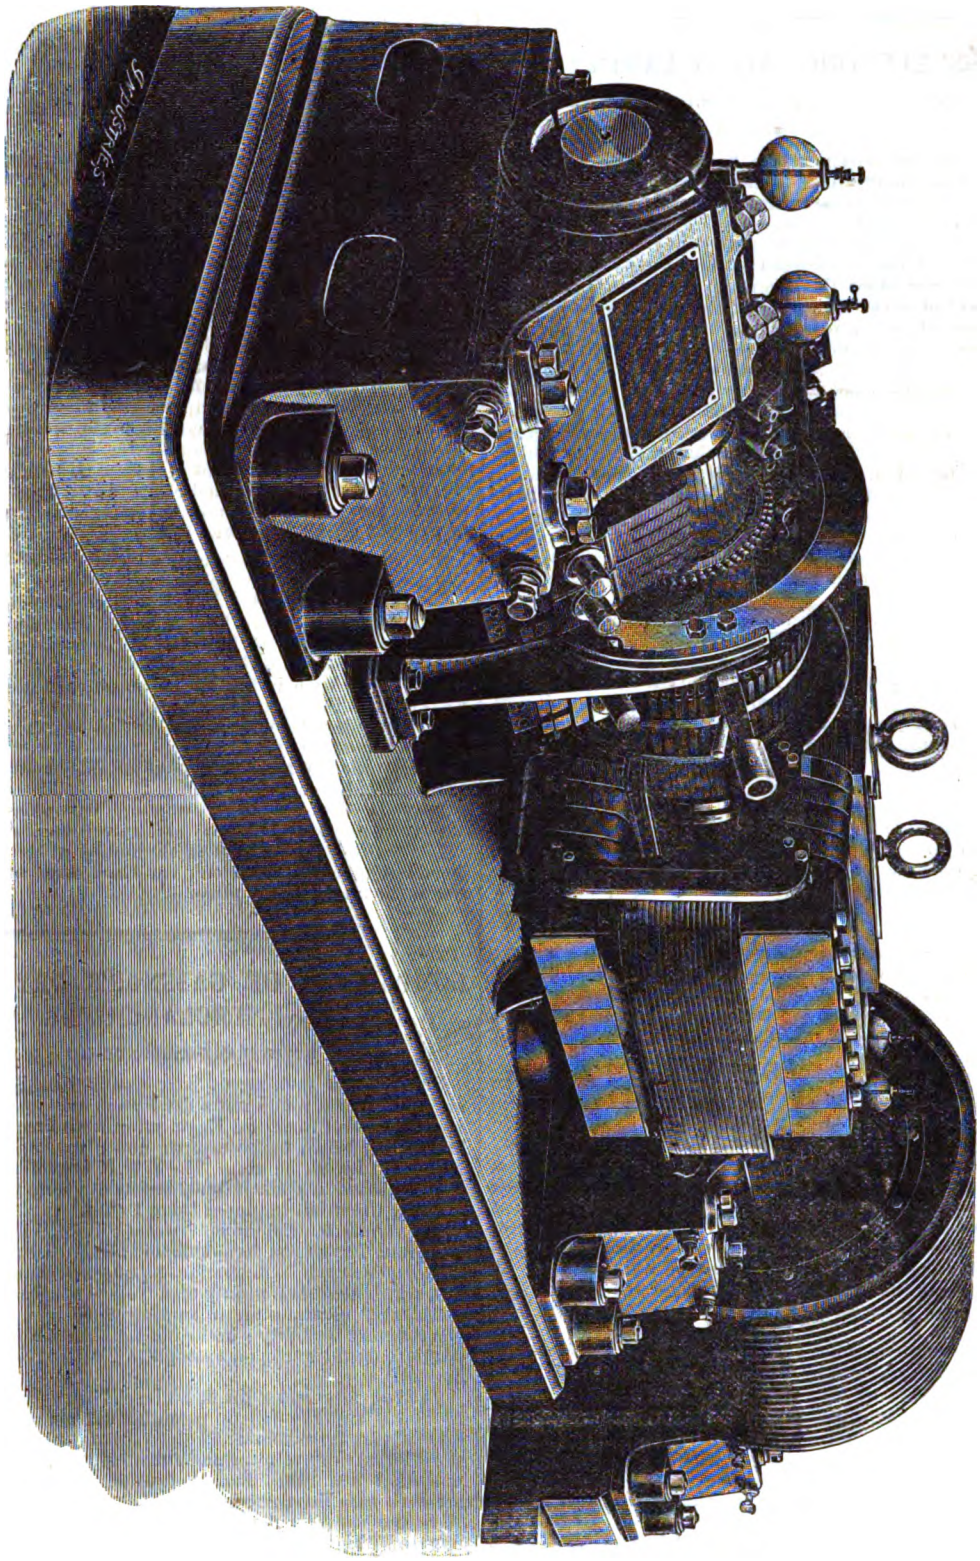
Next to the cut-out comes the current indicator, which is simply a solenoid of nine turns, through which the whole current passes. The core is attached by chain-gear to the pointers, of which there are two, mounted on one spindle. One pointer and dial is placed in the engine-room, and the other in the furnace-room. The gearing of the spindle is calculated so that the range of the instrument up to 8,000 amperes extends over the entire circle of 360deg. The construction of the solenoid for this indicator is somewhat novel. It is cut out of a cylinder of cast-copper by means of a parting tool in a screw-cutting lathe.

There are two furnace-rooms, each containing six furnaces, and the conductors, after leaving the current indicator, pass right across the two rooms at a height somewhat above the attendants' heads. The current is supplied to the furnaces as follows: Each furnace-pit consists of a long trough built of fire-brick, the ends being closed by cast-iron pipes, through which carbon electrodes are arranged, so that they can be moved lengthways to and fro by the attendant in charge. It will be remembered that one of the main features of the Cowles' invention is the use of limed charcoal as a lining for their furnace. They thus obtain a highly refractory non-oxidising lining, which is also a non-conductor of electricity, as the lime prevents the particles of carbon fusing together, and thus forming a continuous conductor, which would otherwise short circuit the furnace and be consumed under the action of the current, instead of the latter performing its proper duty of maintaining the furnace contents at the required high temperature. The electrodes, each of which consists of nine carbon rods attached to a cast-iron head mounted on a copper rod passing through the above-mentioned cast-iron pipes, are each provided with flexible copper wire cable connections, having an attachment sliding along the conductors, passing overhead and somewhat behind them. When it is desired to supply the current to any one furnace, the attachments are slid into position opposite it and clamped fast to the conductors. To start the furnace, the electrodes are brought together so as to touch, and then separated until the whole of the contents of the furnace between them is an incandescent mass at the required high temperature. The working of a charge in the furnace is carried out as follows: The bottom of the empty furnace is covered with limed charcoal, the electrodes are brought into position, and a former or iron box, without top or bottom, and of a size determined by the space to be occupied by the charge is placed in the furnace; the ends of this sheet-iron box are arched out so that it can be dropped over the electrodes. The furnace lining of limed charcoal is then rammed up in the space between the iron former and the furnace balls. The space inside the box is filled with the furnace charge, which, when ferro-aluminium is to be produced, consists of a mixture of charcoal, bauxite, and iron turnings, but when the cupro-aluminium is required, granulated copper is substituted for the iron turnings. When the furnace lining and contents are brought up to the proper level, the iron former is carefully lifted, much as a moulder draws a pattern from the sand. The cover is then lifted on to the furnace, and it is then ready for the electric current. This at first is kept down to 3,000 amperes, but as soon as the charge is thoroughly burned

* Paper read before the British Association at Bath.

Digitized by Google

through, and the furnace contents become incandescent throughout, the current is increased to 5,000 amperes, and in about one hour the reduction is complete. The reduced aluminium trickles through the furnace contents and collects at the bottom below the electrodes, from which in the furnaces last constructed it can be tapped out continuously. Mr. Cowles believes that the temperature of the centre of the furnace is so high that both the reduced aluminium and the metal with which it is to be alloyed are vaporised and combine as a chemical compound when in this condition, being condensed in the upper and cooler part of the furnace, and from thence passing down the sides to the bottom. The working of the furnace when cupro-aluminium is to be provided leaves nothing to be desired. The current can be steadily increased. Towards the commencement and towards the end of the reduction the current is extremely constant, so that the load on the boilers, engines, and dynamos is fairly steady throughout, but when making ferro-aluminium, the conductivity of the furnace contents varies through very wide limits, and this brings heavy strains both on to the steam-engine and dynamo, which must be met by correspondingly increased strength of parts. The chief feature of the process, which strikes a visitor to Milton works, is the small number of men necessary to work the process. Two men in the engine and dynamo room, one man at the boilers, and one boy to manipulate the electrodes of the furnaces, are all that are required for the active part of the operation. Two labourers can easily charge and relime the furnaces, and the remaining staff required for melting down, standardising, and casting into ingots the various classes of furnace products, is correspondingly small. From the experience already gained, the author has no difficulty in designing and constructing engines and dynamos to supply currents of 15,000 or even 20,000 amperes, if such be required for Cowles' furnaces of enlarged size. The electrical difficulties met with in the construction of this large machine have been comparatively small, whereas the mechanical strains have been unexpectedly great, and must be provided for by extreme solidity and massive construction. Recent investigations made in America by Mr. W. J. Keep have shown that the use of ferro-aluminium is likely to be enormously extended when its properties in relation to cast iron are thoroughly understood and appreciated by the engineering world. Mr. Keep is a gentleman who is well known in America, and his statements are entitled to be received with the utmost respect. We already knew in this country that the addition of ferro-aluminium to cast steel or to ingot iron in such proportion that the finished castings will contain not more than one-thousandth part of aluminium produced extraordinary effects, in some cases reducing the melting point 300deg. C., and in all cases imparting great fluidity to the metal, thus giving us sharp castings free from blow-holes, but it has remained for Mr. Keep to show us that the addition of an infinitesimally small percentage of aluminium to cast



CROMPTON'S LARGE DYNAMO.

Digitized by Google

iron insures perfect castings, freedom from blow-holes, and almost all the ills to which the iron founder is subject. Mr. Keep's report is so very full that it is impossible to give any *resumé* of it here. I only call attention to it, and show the extreme importance that ferro-aluminium is likely to assume in future engineering, and that, as far as we know at present, the perfected Cowles' furnace is capable of producing the desired material in any quantity at a moderate cost.

[This question was discussed last week in our contemporary *Industries*, to which we are indebted for the illustration of the dynamo used, as no illustration accompanied the paper.—ED. *E.E.*]

MINERS' ELECTRIC SAFETY LAMPS.*

BY NICHOLAS WATTS, ASSOC.MEM.INST.C.E.

(Fellow of the Institute of Patent Agents, Bristol.)

It is not necessary, the writer thinks, to devote time to inquiry into the reasons which have caused so much attention to be given to the subject of this paper by those interested in coal mining. It will suffice to say that the modifications made from time to time by numerous inventors, by providing additional gauzes and shields, and in other ways to adapt lamps constructed on the principle of the Davy, Clanny, Stephenson, and other like lamps, to the increased velocity (20ft. to 35ft. per second) of the ventilating currents now obtaining in our collieries, have resulted only in rendering such lamps less unsafe than they were, but have failed to make them free from danger, and have in some cases introduced considerable complication and other objectionable features. There being, therefore, apparently not much prospect that a thoroughly satisfactory and safe lamp of the aforesaid types would be forthcoming, it was most natural that the incandescence electric lamp should be seized upon as a probable solution of the difficulty. It appears, on the face of it, most suitable for the purpose, inasmuch as the light depends for its existence on the absence of air, a condition the direct reverse of that necessary to the maintenance of the flame in oil-lamps. The white-hot carbon filament is wholly enclosed in an air-tight glass bulb, from which all the air is withdrawn before the bulb is sealed. No currents of air or explosive mixture can reach it.

Attention having once been directed to the production of electric lamps for miners' use, the field speedily became well tenanted with inventors.

The writer does not propose to refer in detail to the successive developments, but rather to present to the meeting the position as it now is by passing in review some of the best lamps obtainable.

It became clear early in the history of the matter that illumination of collieries by fixed lamps connected to mains was not practicable so far as the working places were concerned. The difficulty of preventing injury to or severance of the wires, combined with other objections, left no doubt on that head. For like or analogous reasons, portable lamps, connected by leads to mains, were not satisfactory. Consequently, all energies were concentrated upon the production of an independent lamp containing its own source of light, and which could be carried about by the miner as freely as a Davy or other like lamp.

How to produce such a lamp, to compare favourably with a miner's ordinary oil-lamp in price, weight, illuminating power, capability of standing rough treatment and hard knocks, and in other respects, became the problem. A good lamp of the Clanny and like types is bought for about 8s., it weighs about 4lb., and gives a light of from 0·4 to 0·5 of a standard candle.

To Mr. Swan belongs the credit of being the first to p.oduce an electric safety lamp with an incandescent lamp as the novel feature thereof. This he did in 1881.

The Swan Lamp (exhibited).—Secondary battery. The elements, lead and lead-oxide, are cylindrical, and are arranged concentrically in each cell. They are contained in a block of gutta-percha, with four cell compartments enclosed in a wooden case. The exciting liquid is dilute sulphuric acid. The cells are recharged by placing the lamp on a stand connected to a dynamo. The lamp proper is attached to the side of the case, and is protected by a "bull's-eye" of thick glass. A light of from one to 1½ c.p. is given for a period of ten hours. The weight is 7lb., and the price 27s. The cost of maintenance is 3½d. per week.

Several hundreds of these lamps are now in use at Risca and elsewhere, and the writer is informed by Mr. Wilkinson, manager at Risca, that they give satisfaction.

The Walker Lamp.—Primary battery. Bichromate-carbon-zinc battery, the carbon being itself the containing vessel. On one side is a strong lens faced by a parabolic reflector, the two being held by a strong brass cylinder attached to the outer case, which is also of brass or copper. The lamp is made in two sizes, of which the smaller weighs 5lb. The battery is composed of two carbon-zinc cells. The liquid used is a mixture of bichromate of potash, nitric acid, and plain sulphuric acid. The E.M.F. is 4 volts, and the current 0·3 of an ampere. The price is—for single lamps, 30s.; for dozens, 27s.; and for grosses, 25s. The light afforded by the small lamp is sufficient to enable ordinary newspaper print to be read at a distance of 6ft. from the lamp for 10 hours. The battery of the larger lamp, which weighs 7lb., has three carbon-zinc cells. The E.M.F. is six volts, and the current 0·5 of an ampere. Price, 48s., 35s., and 32s. respectively. The cost of renewing the chemicals used, the incandescence lamp and incidental repairs, is stated to be not more than ¾d. per day for the small and 1d. per day for the large lamp. The cost of the liquid has been frequently tested, and has come out at ½d. per day of twelve hours' run. The operation of renewing, which is effected in a few minutes, consists in running off the liquid and washing out the cells, running in fresh liquid, and replacing the cover, by which last act the connections between the battery and the lamp are made.

The Pitkin Lamp (exhibited).—Secondary battery of four cells (seen last year in use underground at Tyldesley Colliery by some of the British Association). The weight of this lamp is 8lb., and the price £2. 2s. Illuminating power, four to five candles; a reflector is employed to concentrate the light. The battery is composed of four cells, each having eight plates or fingers, the elements being peroxide of lead and spongy lead. The battery takes eight hours to charge. Mr. Pitkin estimates the life of the battery at about two years. E.M.F., eight volts; current, 0·4 of an ampere. The Pitkin lamp is furnished with a switch, and a resistance to regulate the expenditure of the E.M.F., which, if allowed to act without check would, when the battery was started, destroy the filament. Mr. W. W. Hood, Llwynypia, tried fifty Pitkin lamps, and found that the switch was a difficulty. The men, unless very careful, put on the switch too full, and broke the filament.

The Schanschieff Lamp (exhibited).—Primary battery. The exciting liquid employed is a solution of basic sulphate of mercury in the acid sulphate, one part of the salt being entirely dissolved in three parts of water (according to Schanschieff's patent). The battery can be charged The battery can be charged in fifteen seconds. The elements are zinc and carbon; a single liquid only is employed, and no porous cells, producing resistance and causing waste of energy, are required. The weight, with a battery of four cells, is 4½lb. Each cell takes five fluid ounces of the mercurial solution. The light ranges from 1½ to 2 c.p. The consumption of zinc is ½lb. per shift, or ¼lb. for 48 hours (six shifts of eight hours). The liquid is supplied at 5s. a gallon, and is said to be worth, when spent, 4s. 3d., in consequence of the solid residue and free mercury precipitated by the action of the cells. The working cost of the 4-cell lamps for six shifts of eight hours is 5d., or ¼d. for one shift. In some forms of the lamp the solution occupies a little less than half the height of each cell, and the elements occupy the other half or opposite end of the cells. Thus the lamp is capable of being put out of action by inverting it. The liquid is changed every eight hours. The price is 30s.

The New Portable Electric Lamp and Power Syndicate Company's Lamp (exhibited).—The battery is secondary, and consists of two cells, the elements being lithanode (peroxide of lead) and spongy lead. The weight of the lamp is 4½lb. The light given is one candle over a period of 10 to 12 hours. The battery takes five hours to charge, the cost of recharging being 3d. per week. The price is £1. 1s. The lamp is fitted with an automatic arrangement in connection with the incandescent lamp, whereby, if the outer casing of toughened glass be broken, the current is cut off, and explosion of five-damp guarded against.

The question, Which is the most suitable battery for miners' lamps? though keenly debated, has not yet been finally settled. The secondary battery is, doubtless, more durable, but where dynamos are not already employed the primary battery will find favour.

The position of the light on the top, or at the side of the case, has given rise to much discussion; but the balance of opinion is that the side is the most suitable place.

* Paper read before the British Association at Bath.

COMPARISON OF GASSNER'S DRY CELLS WITH LECLANCHE'S.*

BY W. LANT-CARPENTER, B.A., B.SC.

Shortly after their recent introduction into England, two of Gassner's dry cells, a round and a flat form, were brought to the Hanover-square School of Electrical Engineering, with a request that they should be carefully tested and compared under varying conditions with the No. 2 size Leclanché cell. The E.M.F.'s were taken by Law's condenser method, and the internal resistances were measured by Kempe's method, the shunt employed being 1 ohm.

The results for the round Gassner cell were 1·317 volts, and 0·205 ohm, and for the flat form 1·52 volts and 0·7 ohm respectively. No attempt was made to determine the composition of the contents of the cell, which consisted mainly of a yellow opaque somewhat stiff jelly, remarkably constant under varying conditions of atmospheric temperature and humidity; hence the cells could be placed in any desired position, on their side, for example, a great convenience where space is limited.

The flat form and a No. 2 Leclanché were each circuited through 10 ohms, and the fall in potential difference observed at frequent intervals for three hours. The curve representing the rate and amount of fall of the dry cell was much more regular, and showed a total fall somewhat less than that of Leclanché. Both cells, after six days interval, were short circuited through 2 ohms for two minutes, and their recovery from polarisation observed at frequent intervals for 65 minutes. This caused a fall of 0·21 volts in the dry cell, and of 0·552 volts in the Leclanché; the curves of recovery showed that while the flat dry cell recovered 85 per cent. of this loss in 6½ minutes, and nearly the whole of the remainder in the succeeding 10 minutes, the Leclanché cell required 18 minutes to recover the same proportion of its loss, and 30 minutes to arrive at the same E.M.F. as the dry cell. The latter, however, did not alter appreciably afterwards, while the Leclanché continued to recover slowly for some hours.

The two dry cells, and two No. 2 Leclanché cells, were then short circuited through 1 ohm for one minute, and frequent throws of the galvanometer were taken, to determine the respective rates of recovery of polarisation. The results were very similar, both dry cells recovered the greater part of their lost E.M.F. in seven minutes, and the sub-

* Paper read before the British Association at Bath.

Digitized by Google

sequent recovery was very slow, while the two Leclanché's required at least double the time to recover in the same proportion.

The resistance of a ringing bell, determined by the reproducod deflection method, was ascertained to be 20 ohms. The same four cells were then circuited through 20 ohms for 168 hours each, and observations of their potential differences were made, with the annexed results

Four cells circulated through 20 ohms potential difference at terminals in volts.

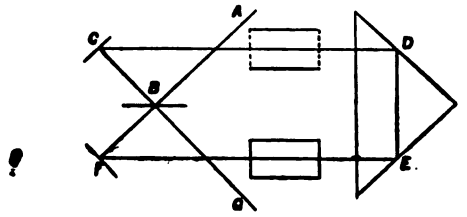
114 0	1·33	1·24
117 0	1·34	1·25

It appears from all these results that the round form of Gassner's dry cell polarises less than a No. 2 Leclanché, and is also of considerably lower internal resistance (the average value being 0·25 ohm); further, that although the dry cell takes somewhat longer to completely recover its E.M.F. when the circuit is opened, the rate of recovery is more rapid than that of the Leclanché for the first five or ten minutes. The flat form of dry cell appears to behave in most cases not quite so well as a No. 2 Leclanché, the internal resistance being about the same—viz., 0·6 ohm. I should add, in conclusion, that the measurements here described were made under the superintendence of Mr. E. C. Rimington.

IS THE VELOCITY OF LIGHT IN AN ELECTROLYTIC LIQUID INFLUENCED BY AN ELECTRIC CURRENT IN THE DIRECTION OF PROPAGATION.*

BY LORD RAYLEIGH.

The question here proposed has been considered by Roite (Pogg. Ann. 150, p. 164, 1873), and by Lecher (Rep. de Phys. 70, p. 151, 1884).† My experiments were made in ignorance of the work of these observers, and the results would scarcely be worth recording were it not that the examination seems to have been pushed further than hitherto. It may be well to say at once that the result is negative. The interference fringes were produced by the method of Michelson, as used in his important investigation respecting "The influence of motion of the medium upon the velocity of light."‡ The incident ray, *a b*, meets a half-silvered



surface at *b*, by which part of the light is reflected and part is transmitted. The reflected ray follows the course, *a, b, c, d, e, f, b, g*, being in all twice reflected at *b*. The transmitted ray takes the course, *a, b, f, e, d, c, b, g*, being twice transmitted at *b*. These rays, having pursued identical paths, are in a condition to form the centre of a system of fringes, however long and far apart may be the courses, *c, d, e, f*. There is here nothing to distinguish the ray, *a, b*, from a neighbouring parallel ray. The incident plane *wave front* perpendicular to *a, b* gives rise eventually to two coincident wave fronts perpendicular to *b, g*. With a wave incident in another direction the case is different. The two emergent wave fronts remain indeed necessarily parallel, both having experienced an equal number of reflections (4 and 6). But there will exist in general a relative retardation of amount (for wave fronts perpendicular to the plane of the diagram) proportional to the deviation from the principal wave front. Hence, if the incident light comes in all direction, a telescope at *g*, focussed for infinitely distant objects, reveals a system of influence bands whose direction should be vertical, if the adjustments could be perfectly carried out in the manner intended.

The success of the method does not require the complete symmetry of the diagrams. If the reflections at *d, e* are effected by a right-angled prism, it is necessary that *c, d, f, e*, be parallel to one another, but not that they be parallel to the surface, *b*. Supposing all the surfaces to remain vertical in any case, the positions of *b, f*, and the incident ray, *a, b*, may be chosen arbitrarily. If the distance, *d, e*, between the parallel courses is not closely prescribed, *one* adjustment by rotation of the mirror, *c*, will suffice. In my experiments the optical parts were mounted upon a large iron plate, so that the movable pieces, *c, d, e*, could be shifted without loss of level. The incident ray, *a, b*, was defined by a small hole near the paraffin-lamp which served as a source of light, and by the centre of moderately large circular aperture perforated in a screen and illuminated when necessary with a candle. The mirror, *c*, was then rotated, until the rays, *c, d, f, e*, were parallel. This was tested by observing the equality of their mutual distances near the extremities of their course.

* Paper read before the British Association at Bath.

† Mr. Wilberforce has experimented upon displacement currents in a dielectric (Camb. Phil. *Trans.*, t. xiv., p. 170, 1887).

‡ *American Journal*, xxxi., p. 377, 1886.

Digitized by Google

If the distance between the parallel rays is prescribed, the adjustment is more troublesome. The line, *f e*, being fixed, sights are laid down defining the desired position of *c d*. These sights, as well as those before referred to defining the incident ray, have now to be brought to apparent superposition as seen by an eye looking along *d c*. For this purpose *two* conditions have to be satisfied by, and two motions must be provided for, the mirror, *c*. One of these should be a movement of rotation, and the other of translation in a direction nearly perpendicular to the plane of the mirror. Thus the mounting may consist of a circular turntable resting upon the iron plate, the curved edge of which is guided by a V cut out of a flat piece of metal and clamped to the plate. In each position of the V the angular motions are easily swept over, and the double adjustment is effected without much difficulty. When the parallelism of the rays is secured, the insertion of the reflecting prism is all that remains. The adjustment of this is best effected with the eye at the observing telescope, which at this stage should be focussed upon the small aperture in the neighbourhood of the flame. By a motion of the prism parallel to its hypothenuse the two images are brought to coincidence,* and then the bands appear, if not at once, when the telescope is accommodated for infinitely distant objects.

The half-silvered central plate would be at its best if it reflected light of the same intensity as it transmits. I have generally found the reflection on the side next the air more powerful than upon the side next the glass, so that the ideal would require the geometric mean of the two reflections to be equal to that of the two transmissions. A very slight silvering is all that is wanted, such as from its want of coherence and brilliancy would be useless for other purposes; and the bands appear tolerably black, even though the interfering lights are of decidedly unequal intensities. There is, of course, also a reflection from the unsilvered surface of the plate. In my apparatus, owing to a want of parallelism, this image was distinctly separated from the other. The two back reflectors were of flat glass, silvered by the milk-sugar process, and used as specular.

The imperfections of the surfaces disturbed the formation of the bands from full accordance with theory. The definition was usually better when the pencils were limited, as by the screens employed to define the incident ray than when all destructions were removed. The final adjustments for the distinctness and desired width of bands were made with the eye at the telescope by shifting the reflecting prism, and occasionally by slight displacements of one of the other reflectors. The tubes enclosing parts of *c d*, *f e*, and containing the electrolyte (diluted sulphuric acid of nearly maximum conductivity) were closed at the ends by plates of parallel glass. The current entered by lateral attachments, so arranged that liquid (or gas) rising or falling from the platinum electrodes would not at first enter the operative part of the tubes. The diameter of the tubes was about ¾in., and the effective length about 11in.

It will be sufficient to give the details of one experiment. The two tubes were connected in multiple arc, and, of course, in such a manner that the current travelled in opposite directions. The magnitude of the whole current (say from eight Grove cells) was 1·5 amperes, so that the current *density* in amperes per square cm. was

$$\frac{\cdot 75}{\pi \times \cdot 38^2 \times 2\cdot 54^2} = \cdot 26.$$

Now, one of the interfering rays travelled 22 inches, or 56 centimetres, with the current, and the other ray the same distance against the current. On *reversal* of the current no shift of the bands could be perceived, under conditions where a shift of $\frac{1}{10}$th† of a band must have been evident. Hence, we may conclude that a current of the above-mentioned density does not accelerate, or retard, the propagation of light in the ratio of $\frac{1}{10}$th λ to 224 cms. In the liquid we may take $\lambda = 4 \times 10^{-5}$ cm.; and if we reduce the result so as to correspond to density unity, we may say that in dilute sulphuric acid a current of one ampere per square cm. does not alter the velocity of light by one part in 13 millions, or by 15 metres per second.

It would probably be possible to carry the test 10 or 15 times further by the use of much longer tubes and a more powerful battery; but there seems to be no sufficient encouragement at present to make the attempt. The case would, of course, be very different were anyone to show by *a priori* argument a reason for expecting an effect of this order of magnitude.

VORTEX ANALOGUE OF STATIC ELECTRICITY.‡

BY PROF. W. M. HICKS, F.R.S.

Consider two bodies touching one another placed in an infinite fluid, and with a vortex filament, the ends of which are one on one surface, the other on the other. If now the surfaces be separated from one another, there will be formed, at the point where they separate, a hollow vortex filament stretching from one to the other, with rotation equal and opposite to that of the original filament. As the bodies are moved apart these filaments will not, in general, take up a position of rest. If the strength of the original filament be very great, or if there be several of them, the resulting hollow vortex will, through instability, split up into a number of smaller ones. If the resulting number be very large, they will ultimately take up some position of stable equilibrium. What the distribution in this will be, I cannot say, but the following is one state of equilibrium, and, probably, although I have not proved it, a stable one. The two sets of filaments will be mixed up with one another, and each will distribute itself according to the same law as the distribution of lines of force between the two bodies supposed equally and oppositely electrified.

In the case of the original filament, as the surfaces are further and further separated, their sections become smaller and smaller. This is, however, not the case with the hollow filaments. Their section depends only on the pressure of the fluid and their circulation, and, as these remain constant, the areas of their section also remain so. In such a hollow vortex the pressure inside sinks to zero. Consequently the portion of the surface on which it abuts experiences a diminution of pressure, a diminution which is the same at all distances. The two bodies are therefore attracted towards one another. Moreover, as the two bodies separate further, the distribution of the filaments being the same as that of electrical lines of force, and the diminution of pressure for each line being constant, it follows that the force between the two bodies follows precisely the same laws as the force between the two bodies supposed equally and oppositely electrified.

If another surface be brought into the presence of the others, some of the filaments would abut on this. These would break off, rearrange themselves so that some of the filaments would end on it, and an equal number start from it. Call those ends of the filaments positive at which the rotation, looked at *from* the surface on which they abut, is right handed; and those ends negative at which the rotation is left handed. The two ends of any filament will then always be of opposite name.

The analogy with electrical action is then close. Two bodies, A B, brought in contact touch in innumerable points. Owing, possibly, to the different states of motion of the ether at their surfaces, a state of equilibrium is set up, consisting of a kind of sifting of vortex motion already subsisting, so that, on the whole, more lines go from A to B than *vice versa*. This is E.M.F. of contact. Separate the bodies, one has a number of positive ends of hollow filaments, and the other an equal number of negative ends. *The bodies are equally and oppositely electrified.* The force, in its hydro-dynamical case and in its electrical analogue, follow the same laws. Bring into the field another surface, C. The filaments rearrange themselves as mentioned above, the negative and positive ends abutting on C being equal. *This is induced electricity.* If the surface C consists of a large number of small unconnected surfaces, the filaments will arrange themselves in some manner depending on the sizes and distances of the unconnected parts, the field will be disturbed in a similar way to that in an electric field into which a different dielectric is placed. This is the analogue of electric strain in a dielectric. So far, the ground is fully safe; the succeeding remarks must be regarded as speculative.

Returning to the case of the two separated surfaces, A and B, what will happen if they be connected by a third surface—say, to fix ideas, a long narrow cylinder or wire? It is not so easy to say certainly what the exact rearrangement will be. It would seem very probable that the hollow filaments near the wire would at once be replaced by circulation round the wire. In this case the solid filaments must rotate as a whole round it, while, at the same time, although this has not been proved, they will contract their ends, move along until they come together, form a ring, and get mixed up in the surrounding fluid. This would correspond to the *current of discharge*. But notice that if this is so, the fluid outside the wire rotates round the wire while a stationary state is being reached, and as we know that the field round a current is a magnetic field, it follows that the *analogue of a magnetic field is a flow along the magnetic lines of force*. It may, however, be further necessary that these streams must contain vortex filaments moving with the fluid, their axes at every point being perpendicular to the lines of force there.

If the field is determined by the flow of fluid independently of the vortex motion, it is not easy to see the hydro-dynamical analogue of the induction of currents, when, say, a wire moves across a uniform magnetic field. If, however, the vortex filaments, as above, are a necessary adjunct, it is conceivable how a movement of the wire across the lines of flow and amongst the filaments produces an instantaneous disarrangement, which will travel through the vortical fluid with the velocity of propagation of transverse vibrations in a vortical fluid. That is in the ether, as Sir W. Thomson has shown, with the velocity of light.

It is difficult to see any analogue to the rotation of the plane of polarisation of light by a magnetic field.

ON AN APPARATUS FOR DETERMINING TEMPERATURE BY THE VARIATION OF ELECTRICAL RESISTANCE.*

By Wm. Shaw, M.A., Lecturer on Physics in the University of Cambridge.

This apparatus is designed to measure to a high degree of accuracy the mean temperature of a large burette immersed in a water bath. A Wheatstone quadrilateral is formed by joining the ends of a platinum wire about 30in. long (resistance about 11 ohms) to those of a platinum silver wire, B, C, D, A. The platinum wire is base, and the alloy is silk-covered ·007in. in diameter. Its resistance is 13·5 ohms per metre. At A C and B D respectively, battery and galvanometer wires are soldered. The lengths of the wires are so arranged that for some temperature near 15deg.C. there is a perfect balance indicated in the bridge. The wires are laid in parallel lengths, and disposed upon a strip of pure indiarubber about ¾in. wide in the manner indicated in

* It should be noticed that if the object were at infinity, or if with the aid of a collimating lens an image of it were thrown to infinity, the two images as seen focussed through the telescope would overlap in any case. For it may be proved that whatever may be the positions of the fine reflecting surfaces, the two emergent rays, corresponding to any incident ray, are necessarily parallel.

† Probably I might say $\frac{1}{20}$th, but it is best to be upon the safe side. When the contact was maintained a slight shift was observed, but in a direction independent of that of the current.

the figure. The indiarubber is painted with a solution of indiarubber in benzene, and a second strip, similarly painted, is laid down upon it, and the wires are thus completely enclosed; the strip continues 18 metres at each end beyond the junctions of leading wires, so that the whole length of strip is about 5½ft., and from the two ends the galvanometer and battery leads respectively project.

A very flexible quadrilateral is thus obtained in the form of a ribbon, which can be wrapped round any apparatus whose temperature is required. Since the two wires, which together form the quadrilateral, have different temperature co-efficients, there is no balance except for one particular temperature, but the balance can be restored by shunting either the wire, A B, or the arm, B C, by connecting a resistance-box in a suitable manner with the projecting leads. The

resistance of the shunt required to produce a balance can be employed to indicate the temperature when the instrument has once been graduated. The graduation of the apparatus exhibited was made for the author at the Cavendish Laboratory by Mr. J. W. Capstick, demonstrator at University College, Dundee. The ribbon was wound round a metal cylinder, and the whole immersed in ice or water, and a number of readings of the shunt taken at different temperatures between 0deg. and 28deg.C. The conductivity of the shunt at different temperatures is very nearly represented by a straight line cutting the zero line at the neutral point, 15-16deg.C. The maximum divergence from the straight line corresponds to the temperature difference of a fifth of a degree between 0deg. and 151-6deg., and to about a tenth of a degree between 15-16deg. and 28deg. In the graduation the temperatures are referred to the Kew standard by means of mercury thermometers previously compared at Kew. The temperature can be read with a suitable galvanometer to about the 500th of a degree.

THE PROTECTION OF ELECTRIC LIGHT STATIONS FROM LIGHTNING.*

BY W. J. JENKS.

(*Concluded from page 208.*)

The most desirable method in an electric light station, or, in fact, in connection with any building to be protected, is to connect with as many good grounds as are available. From the centre of distribution, or lightning arrester, a ribbon of copper or galvanised iron, say, $\frac{1}{16}$ inch thick and an inch wide, should take as straight a route as possible to the points of contact with pipes or ground plates. Smaller copper tapes may lead from the main ribbon to each of the connections, and, after making the contacts bright, they should be carefully soldered, and the whole may then be covered with tape or other convenient insulation. It is always better in stations or dwellings to insulate these ground wires on porcelain or other non-combustible material, so that in case of corrosion or any accident, the setting up of an arc between the disjointed ends shall not fuse wood or other combustible substances near them.

In the case of rods, however, on the outside of buildings, insulation is generally not only unnecessary but foolish and possibly dangerous. With few exceptions, all metallic surfaces or masses employed in the construction of buildings should be carefully connected with the rod itself; one very important object is thus to attain the keeping of all the metal surfaces of the building at the same potential as the earth, and thus giving the lightning flash a large capacity for conduction to ground.

The exceptions to connecting iron about buildings with the rods which protect them have been noted by eminent authorities as balconies or other masses of metal upon which people may stand at the time of electrical discharges, and thus form terminals to receive the flash on its way to earth.

An occasional test of the earth connections is one of the important things to the central station manager. The most carefully-made grounds may become disconnected by corrosion or mechanical injury of the conductors. Siemens has suggested a valuable method, which, though somewhat complex, can be readily mastered and applied in a practical form. A simple way is to so arrange the rigid ground wires as that a galvanometer and Leclanché cell can be readily connected with two independent grounds, and by a deflection, when the conductors are so coupled as to complete the circuit through the earth, show at any time whether any change in their resistance has taken place.

The form of arrester most suitable for the protection of central station apparatus has for the past six months been the subject of much careful thought. The peculiar experience of many central stations, and particularly of those which have adopted the municipal system, seemed at first only to add complexity to the problem. The extraordinary precautions taken in insulating this system of widely radiating lines have demonstrated in the first place that these lines covering sometimes several square miles of territory, serve as a gathering ground for charges which often concentrate at the dynamo or act as connecting links through the dynamo between the widely separated clouds. In some cases where armatures have thus been destroyed, it seems to be impossible to account for the peculiar features on any theory except that there was no special tendency to jump to earth, but that the current used the dynamo only as a connecting link between the widely separated points brought near together by lines of wire diverging from the central station.

Feeling that this was one of the questions upon which the most exhaustive study should be extended, the matter was some months ago referred to Mr. Edison, and, upon thinking it over carefully, seemed to him clearly analogous to his experience in the case of the protection of the phonoplex telegraph system from lightning. This has always been found a difficult matter, in the same way that the protection of the system of alternating-current transformers has thus far proved an unsolved problem. The condenser which is necessary to the action of the phonoplex, with its plates of large capacity separated only by a thin insulation, seem to invite the atmospheric discharge towards the easy channel; and then, when the capacity of the condenser was filled, the arrested energy found its way in a flash through the insulation. Thus, also, large numbers of converters are on record as having been burned out by atmospheric flashes almost as fast as they could be put up. In the dynamo armature, considerable surfaces of wire, connected directly with the lines, are brought into immediate proximity with the core, the shaft, the bus frame, and sometimes with water pipes, thus inviting a flow of current to the point of weak insulation. Mr. Edison's idea is the providing of a point of still weaker insulation before the dynamo is reached.

No definite form of future central station arrester has yet been decided upon, but it is probable that the air condenser will be used, having numerous ground plates separated from those of the line by a very small air space, perhaps $\frac{1}{50}$th of an inch. In case of a discharge which might be followed by the line current, a fusible wire will be used, situated so as to melt and open the circuit before damage could be done.

The fuse can be instantly replaced even while the shower is in progress, or, if necessary, the arrester itself can be changed in a few seconds. Working models embodying this idea are soon to be sent by Mr. Edison to some of the stations which have been most afflicted for practical trial.

In addition to this central station protection applied to the bus bars as a distributing point for a general system, it is very desirable that arresters be placed at several points on the conductors of a three-wire or midway of the resistance of each circuit of a municipal system of any size. It is suggested that one three-wire arrester be placed on each section of main in some convenient and accessible building where a ground which is unquestioned can be readily secured. This special arrester will also be provided with fusible cut-outs, enclosed in a porcelain case sufficiently ventilated to prevent any breakage by explosive action, and to prevent a possible communication of any fire from an arc. With a dozen or twenty of these small arresters, which can be periodically inspected after severe showers, in addition to a central station arrester, it is pretty evident that our stations will be protected far better than heretofore, to say the least.

*Abstract of paper read before the Association of Edison Companies.

Wood-Sawing Motor.—The proprietor of a saw-mill claims that with a 6 h.p. electric motor he can do more work than with a 10 h.p. steam-engine.

THE ELECTRICAL TRANSMISSION OF POWER.*

BY PROF. AYRTON, F.R.S.

What is power, and why should we wish to transmit it? Power has one very definite meaning in science, and several rather vague meanings in practice. We speak of a powerful athlete, the power of the law, we sing of the power of love, we say knowledge is power, and so on, using the word in several different senses. Now, in spite of the fact that a general audience feels a little anxious as to what troubles may be in store for it when a lecturer begins by being painfully exact, my telling you that by "power" an engineer understands, the rate of doing work, will not, I hope, make you fear that my remarks will bristle with technicalities.

When you walk upstairs you exert power, only, perhaps, the one-twentieth of a horse when you go up slowly talking to other people. But when you run upstairs because you have forgotten something that you intended to bring down, then your exertions represent perhaps one-tenth of a horse-power. You only get to the top of the stairs in either case, but the breathless sensation of running fast upstairs tells you that the more quickly you go the harder you are working. A person exercises power in the engineer's sense when he exerts himself physically, and the greater the exertion the greater the power. The exercise of power by the ruling classes, however, is unfortunately not necessarily accompanied by any exertion, physical or mental.

Probably the most familiar example of exerting power at a distance, that is, of transmitting power, is pulling a handle and ringing a bell in another room. I pull the handle, exerting myself slightly, and as the result the bell at the other end of the platform rings. Were not this such a very familiar operation, I would call it experiment No. 1. You have, doubtless, all of you performed this experiment several times to-day, and, what is all important with an experiment, performed it successfully.

And yet it was not until just 100 years ago that it dawned on people that if one person, A, wanted to attract the attention of another person, B, the place where the bell ought to sound was where B was, and not where A was. Indeed, in many English villages down to the present day the knocker principle of attracting attention is alone resorted to, with the result which you may remember happened when Mr. Pickwick was staying in Bath at lodgings in the Royal-crescent, and Mr. Dowler undertook to sit up for Mrs. Dowler, but "made up his mind that he would throw himself on the bed in the back room, and *think*, not sleep, of course. . . . . Just as the clock struck three there was blown into the crescent a sedan-chair, with Mrs. Dowler inside, borne by one short, fat chairman, and one long thin one. . . . . They gave a good round double knock at the street door. . . . . 'Knock again, if you please,' said Mrs. Dowler, from the chair. 'Knock two or three times, if you please.' The short man stood on the step, and gave four or five most startling double knocks of eight or ten knocks apiece, while the long man went into the road and looked up at the windows for a light. Nobody came. It was as silent and as dark as ever." But the tall thin man, you may remember, "kept on perpetually knocking double knocks of two loud knocks each like an insane postman," till Mr. Winkle, waking up from a dream "that he was at a club where the chairman was "obliged to hammer the table a good deal to preserve order," met with the catastrophe which the readers of Mr. Pickwick will remember. This episode shows what it is to have plenty of power and no means of transmitting it.

But if some houses can still dispense with mechanical or other methods of transmitting power, even to ring bells, factories cannot. The looms, the lathes, or whatever the machinery used in the factory may be, must either be worked by hand or foot, in the old style, or it must be connected with the steam, gas, or water engine in the new. On entering a large factory, you see lines of rapidly-rotating shafting, and a network of rapidly-revolving belting, all employed in transmitting power. As a contrast to this, I now throw on the screen a photograph of Sir David Salomon's workshop at Tunbridge Wells, in which every machine is worked by a separate electric motor, thus saving to a great extent the loss of power that usually accompanies the mechanical transmission.

In America there are 6,000 electro-motors working machinery, in Great Britain hardly 100.

But it is not only in transmitting the power from the steam, gas, or water engine of a factory to the various machines working in it, that electricity can be utilised. An incredible amount of power is daily running to waste in this and other countries, because many of the rapid streams of water are too far away from towns for their power to have been hitherto utilised.

The holiday tourist, when admiring the splashing water dashing over the stones, hardly realises that the money loss is as if the foam were composed of flakes of silver.

If we take as a low estimate that a large well-made steam-engine burns only two pounds of coal per horse-power per hour, the coal consumption which would be equivalent to the waste of power at Niagara would exceed 150 million of tons per annum, which, at only five or six shillings per ton, means some 40 million pounds sterling wasted. And descending from big things to small, the river Avon, flowing through Bath, which, so far from being a roaring cataract, especially in dry weather, pursues its course with only a respectable orderly swish, still represents a certain amount of lost power. It has been estimated that from 25 to 130 h.p. runs to waste at the Bathwick Weir, behind the Guildhall, depending on the season. If we take, as an all round average, that the fall of this weir represents 50 h.p., and that a steam-engine producing this power burns 150lb. of coal per hour, it follows that with steam coal at 16s. per ton, the price at Bath, the waste at Bathwick Weir represents an income of £450 per annum, not a princely fortune it is true, but too large to be utterly thrown away as at present.

This state of things will, I hope, however, be shortly remedied, for, as you will see from the large map on the wall, it is proposed to put up 81 electric arc lamps throughout the streets of Bath, and to supply the 50 h.p. required for these lamps by the fall of the Bathwick Weir, supplementing the fall with a steam-engine at dry seasons.

The next large diagram shows the use that Lord Salisbury has made of the River Lea to electrically light Hatfield House and to supply electric motive power to the various machines working on his estate. The following diagram shows the course of the Portrush electric railway, six and a-half miles long, which is worked by the Bushmill Falls, situated at about one mile from the nearest point of the railway; and lastly, this working model on the table, kindly lent me by Dr. E. Hopkinson, as well as the diagram on the wall, represent the Bessbrook and Newry electric tramway, a little over three miles in length, which is also worked entirely by water-power, the turbine and dynamo which convert the water-power into electric power being at about three-quarters of a mile from the Bessbrook terminus. (Model electric tramway shown in action.)

The newspapers of last week contained a long account of the spiral electric mountain railway that has just been opened to carry people up the Burgenstock, near Lucerne, and worked by the River Aar, three miles away, so that we see electric traction worked by distant water-power is extending. But, splendid as are these most successful uses of water-power to actuate distant electro-motors, it is but a stray stream here and there that has yet been utilised, and countless wealth is still being squandered in all the torrents all over the world.

The familiarity of the fact makes it none the less striking that, while we obtain in a laborious way from the depths of the earth the power we employ, we let run to waste every hour of our lives many, many times as much as we use.

It is also a well-established, time-honoured fact that large steam-engines can be worked much more economically than small ones, and that, therefore, if it were possible to economically transmit the power from a few very large steam-engines to a great number of small workshops there would be a great saving of power, as well as a great saving of time from the workmen in these many small workshops, having only to employ this power for various industrial purposes, instead of having to stoke, clean, repair, and generally attend to a great number of small, uneconomical steam-engines.

When delivering the lecture which I had the honour to give at the meeting of the British Association at Sheffield nine years ago I entered fully into Prof. Perry's and my own views on the subject, and, therefore, I will not enlarge on them now. You can all realise the difference between the luxury of merely getting into a train instead of having to engage post-horses, of being able to send a telegram instead of employing a special messenger, or being able to turn on a gas-tap and apply a match when you want a light instead of having to purchase oil and a wick and trim a lamp. Well, a general supply of power to workshops is to the manufacturer what a general supply of light or a general supply of post-office facilities is to the householder. It is all part of the steady advance of civilisation that leads the man of to-day to go to the tailor, the shoemaker, the baker, the butcher instead of manufacturing his own moccasins and lassoing a buffalo for dinner. And in case any of you may be inclined to think that we have gone far enough in these new-fangled notions, and we are all perhaps prone to fall into this mistake as we grow older, let me remind you that while each age regards with justifiable pride the superiority of its ways to those of its ancestors, that every age will appear but semi-civilised to its great grand-children. Let us accept as an undoubted fact that a general distribution of power would enable the wants of civilised life to be better satisfied, and therefore would greatly benefit industry.

There are four methods of transmitting power to a distance: 1. By a moving rope. 2. By air compressed or rarified at one end of a pipe operating an air motor at the other end. 3. By water forced through a pipe working a water motor. 4. By electricity.

We have an example of transmission of power through a short distance by an endless belt or rope in the machines geared together by belts on this platform, and in the rotatory hair-brushes at Mr. Hall's establishment in the Corridor, Bath. At

* Lecture delivered at the Drill Hall, Bath, on Friday, September 7th, 1888.

Digitized by Google

Schaffhausen, and elsewhere in Switzerland, the principle is employed on a large scale. Spain and other countries use it in connection with the mining operations, and, lastly, wire ropes replace horses on many hilly tramways.

For short distances of a mile or so there is no system of transmitting power in a *straight line* along the open country so cheap to erect, and so economical of power as a *rapidly* moving endless rope; but the other systems give much greater facilities for distributing the power along the line of route, are much less noisy, and far surpass wire-rope transmission in economy when the rope must move somewhat slowly, as in tramway traction, or when the distance is considerable over which the power is transmitted, or when the line of route has many bends.

In the same sense that an ordinary house bell may be considered as a crude example of the transmission of power by a moving rope, the pneumatic bell at the other end of the hall which I now ring by sending a puff of air through the tube is a crude example of the transmission of power by compressed air (pneumatic bell rung). Compressed air is employed to work from a distance the boring machines used in tunnelling; the continuous vacuum brakes used on many of the railways are also probably familiar to you, and the pneumatic system of transmitting power to workshops is shortly to be tried on a fairly large scale at Birmingham.

But distribution of power by water pressure is the plan that has hitherto found most favour in this country. That little water motor at the other end of the platform rapidly revolves when I work this garden syringe, and serves as a puny illustration of the transmission of water pressure (experiment shown). Pressure water has been employed for years on a large scale at Hull for distributing power; also by Mr. Tweddle as a means of communicating a very large amount of power through a flexible tube to tools that have to be moved about, but the grandest illustration of this principle is the vast system of high pressure mains that has been laid throughout London, as you will see from the photograph that I now project on the screen of the map, kindly lent me by Mr. Ellington.

The economy of this system is so marked, and the success that has attended its use so great, that, did I not feel sure that electricity offers a grander system still, it would be with fear and trembling that I should approach the subject of this evening, the "Electric Transmission of Power." *Punch* drew, six years ago, the giant steam and the giant coal looking aghast at the sucking-babe electricity in its cradle. That babe is a strong boy now; let the giant water look to its laurels ere that boy becomes a man. For the electric transmission of power, even now, bids fair to surpass all other methods in (1) economy in consumption of fuel; (2) more perfect control over each individual machine—for see how easily I can start this electric motor, and how easily I can vary its speed (experiment shown); (3) ability to bring the tool to the work, instead of the work to the tool—this rapidly rotating polishing-brush with its thin, flexible wires, conveying the power I can handle as easily as if it were a simple nail-brush; (4) in greater cleanliness—no small benefit in this dirty, smoky age; (5) and lastly, there is still one more advantage possessed by this electric method of transmitting power that no other method can lay claim to—the power which during the daytime may be mainly used for driving machinery, can, in the easiest possible way, be used during the night for giving light. I turn this handle one way, and the electric current, coming by one of these wires and returning by the other, works this electro-motor; now I turn the handle the other way, and the current, which comes and returns by the same wires as before, keeps this electric lamp glowing (experiment shown).

It might be said that the transmission of power by coal gas, which I have excluded from my list, fulfils the condition, but so also does the transmission of power by a loaded coal waggon. In both these cases, however, it is the fuel itself that is transmitted, and not the power obtained by burning the fuel at a distant place.

Let us study this electric transmission a little in detail. I pull this handle, and the bell at the other end of the room rings; but in this case there is no visible motion of anything between the handle and the bell. (Electric bell rung by an electric current produced by pulling the handle of a very small magneto-electric machine.) Whether I ring the bell by pulling a wire, or by sending an air puff, or by generating an electric current by the exertion of my hand, the work necessary for ringing the bell is done by my hand, exactly as if I took up a hand-bell and rang it. In each of the three cases I put in the power at one end of the arrangement, and it produces its effect at the other. In the electric transmission how does this power travel? Well, we do not know. It may go through the wires, or through the space outside them. But although we are really quite in the dark as to the mechanism by means of which the electric power is transmitted, one thing we do know from experience, and that is this: given any arrangement of familiar electrical combinations, then we can foretell the result.

Our knowledge of electrical action in this respect resembles our knowledge of gravitation action. The only think quite certain about the *reason* why a body falls to the ground is that we do not know it; and yet astronomical phenomena can be predicted with marvellous accuracy. I mention the analogy, since some people fancy because the answer to that oft-repeated question "what is electricity?" not only cannot be given exactly, but can only be guessed at in the haziest way, even by the most able, that, therefore, all electric action is haphazard. As well might the determinations of a ship's latitude at sea be regarded as a mere game of chance, because we have not even a mental picture of the ropes that pull the earth and sun together.

This power of producing an action at a distance of many yards, or it may be many miles, by the aid of electricity without the visible motion of any substance in the intervening space is by no means new. It is the essence of the electric telegraph, and electric transmission of power was employed by Gauss and Weber when they sent the first electric message. I am transmitting power electrically whether I now work this small model needle telegraph instrument, or whether I turn this handle and set in motion that little electric fan. (Experiment shown.)

But until about ten years ago the facility that electricity gave for producing signals almost instantaneously at a great distance was the main thing thought of. The electric power consumed for sending the telegraph messages was so small, the amount of power lost *en route* comparatively so valueless, that the telegraph engineer had no need to trouble himself with those considerations that govern us to-day when we are transmitting power large enough to work a factory or an electric tramway. Although there are as many as 22,560 galvanic cells at the Central Telegraph Office, London, which cost some thousands annually to keep in order, what is that compared with the salaries of all the 3,089 superintendents, assistants, telegraph clerks, messengers, and the maintenance of the 1,150 telegraph lines that start from the Central Office?

In all the last three of the systems on my list some form of power, such as flowing water or the potential energy stored up in coal, wood, zinc, or other fuel has initially to be utilised, this power is given to some form of air, water, or electric pump, which transfers the air power to the air, water, or electricity, by which it is conveyed to the other end of the system. There it is reconverted into useful mechanical power by means of an air, water, or electro-motor.

You will observe that I class together air, water, and electricity; but that I do not mean to imply that electricity is a fluid, although in many respects it acts like a fluid, like a fluid of very little mass, however, or, odd as it may seem, like a fluid moving extremely slowly, for electricity goes round sharp corners with perfect ease and without any of the phenomena of momentum possessed by rushing water. But what I particularly wish to impress on you by classing air, water, and electricity together is that electricity is not, as some people seem to think, a something that can be burnt or in some way used up and so work got out of it. Electricity is no more a source of power than a bell wire is; electricity is a marvellously convenient agent for conveying a push or a pull to a great distance, but it is not by the using up of the electricity that electric lights burn or that electro-motors revolve. It is by the electricity losing pressure, exactly as water loses head when turning the miller's wheel as it flows down hill, that work is done electrically.

This model shows in a rough symbolical way what takes place in the transmission of power whether by air, water, or electricity (model shown). The working stuff, whichever of the three it may be, is first raised in pressure and endowed with energy, symbolised by this ball being raised in the model from its original position to a higher one; it then gradually loses pressure as it proceeds along the tube or wire which conveys it to the other end of the system, the loss of pressure being accompanied by its giving up power to the tube or wire and heating it. This is shown in the model by the ball gradually falling in its course. At the other end there is a great drop of pressure corresponding with a great transference of power from the working stuff to the motor, and finally it comes back along the return pipe or wire, losing, as it returns, all that remains of the pressure given to it initially by the pump. The ball has, in fact, come back to its original level.

The problem of economically transmitting power by air, water, or electricity is the problem of causing one or other of these working stuffs, air, water, or electricity, to economically perform the cycle I have described.

In each of the four stages of the process (1) transference of power to the working substance at the pump, (2) conveyance of power to the distant place, (3) transference of power from the working substance to the motor at the distant place, (4) bringing back the working substance, there is loss of power, and the efficiency of the arrangement depends on the amount of these four losses. The losses may be shortly called (1) loss at pump, (2 and 4) loss on the road, (3) loss at the motor.

Until 1870, the pump most generally employed for pumping up electricity and giving it pressure was the galvanic battery, scientifically an extremely efficient converter of the energy in fuel into electric energy, only unfortunately, the only fuel a battery will burn is so expensive. A very perfect fireplace, in which there was very complete combustion and very little loss of heat, but which had the misfortune that it would only burn

Digitized by Google

the very best wax candles, would be analogous with a battery. The impossibility of using zinc as fuel to commercially work electro-motors has been known for the last half century, and the matter was very clearly put in an extremely interesting paper "On Electro-Magnetism as a Motive Power," read in 1857 by Mr. Hunt before the Institution of Civil Engineers, a copy of which has been kindly lent me by Dr. Silvanus Thompson. "Prof. William Thomson (Glasgow)"—I quote from the discussion on the paper—put the matter very pithily by showing that, even if it were possible to construct a theoretically perfect electro-motor, the best that could be hoped for, if it worked with a Daniell's battery, would be the production of a 1 h.p. by the combustion of 2lb. of zinc per hour, whereas with a good actual steam-engine of even thirty years ago, 1 h.p. could be produced by the combustion of exactly the same weight of the much cheaper fuel—coal. This argument against the commercial employment of zinc to produce electric currents is irresistible, unless—and this is a very important consideration, which is only beginning to receive the attention it deserves—unless, I say, the compound of zinc formed by the action of the battery can be reduced again to metallic zinc by a comparatively inexpensive process, and the zinc used over and over again in the battery. If the compound of zinc obtained from the battery be regarded as a waste product, then it would be much too expensive to work even theoretically perfect electromotors, if they were existent, by consuming zinc. Suppose, however, a process be devised by means of which burnt zinc can be unburnt with an expenditure comparable with the burning of the same weight of coal, then it might be that although coal would still form the basis of our supply of energy, the consumption of zinc batteries might be an important intermediary in transforming the energy of coal economically into mechanical energy.

While, then, some experimenters are aiming at possibly increasing the working power of a ton of coal to eight times its present value by earnestly seeking for a method of converting the energy it contains directly into electric energy without the intervention of a wasteful heat-engine, it should not be forgotten that in the cheap unburning of oxidised metal may lie another solution.

The solution of this latter problem is quite consistent with the principles of the conservation and dissipation of energy, since the heat required to theoretically unburn 1lb. of zinc is only one-seventh of that given out by the burning of 1lb. of coal. Further, it involves no commercial absurdity like that found in the calculations given in the prospectuses of many primary battery companies which are based on zinc oxide, a material used in the manufacture of paint, maintaining its present price even if thousands of tons were produced. Unless all those who use primary batteries on this expectation intend to have the painters doing up their houses all the year round, they will find themselves possessed of the stock-in-trade of an oil and colourman on a scale only justified by a roaring business in paint.

Now, about waste No. 3—the waste of power at the motor. That also is gone into fully in the discussion in Mr. Hunt's paper, and Mr. Robert Stephenson concluded that discussion by remarking: "That there could be no doubt, from what had been said, that the application of voltaic electricity, in whatever shape it might be developed, was entirely out of the question, commercially speaking. . . The power exhibited by electro-magnets extended through so small a space as to be practically useless. A powerful electro-magnet might be compared—for the sake of illustration—to a steam-engine with an enormous piston, but with an exceedingly short stroke. Such an arrangement was well known to be very undesirable." And this objection, made with perfect justice against the electro-motor of thirty years ago, might also have been made to all the machines then existing for the mechanical production of electric currents.

I have two coils of wire at the two sides of the platform, joined together with two wires. I move this magnet backwards and forwards in front of this coil, and you observe the magnet suspended near the coil begins to swing in time with my hand (experiment shown). Here you have, in its most rudimentary form, the conversion of mechanical power into electric power, and the reconversion of electric power into mechanical power; but the apparatus at both ends has the defects pointed out by Mr. Hunt and all the speakers in the discussion on his paper—the effect diminishes very rapidly as the distance separating the coil from the moving magnet increases.

As long as electro-motors, as well as the machines for the production of electric currents, had this defect the electric transmission of power was like carrying coal to Newcastle in a leaky waggon. You would pay at least 16s. for your coal at Bath, lose most of them on the way, and sell any small portion that had not tumbled out of the waggon for, say, 2s. a ton at Newcastle, a commercial speculation not to be recommended.

A very great improvement in electric motors was made by Pacinotti in 1860; but although his new form of electro-motor was described in 1864 it attracted but little attention, probably because any form of electro-motor, no matter how perfect, was commercially almost useless until some much more economical method of producing electric currents had been devised than the consumption of zinc and acids. Pacinotti's invention removed from motors that great defect that had been so fully emphasised by the various speakers at the reading of Mr. Hunt's paper in 1857. When describing his motor in the *Nuovo Cimento*, in 1864, he pointed out that his principle was reversible, and that it might be used in a mechanical current generator. This idea was utilised by Gramme in 1870, who constructed the well-known Gramme dynamo for converting mechanical into electric power, a machine far more efficient than even Pacinotti had contemplated, and gave the whole subject of electrical engineering a vigorous forward impulse. Every subsequent maker of direct-current dynamos, or motors, has followed Gramme's example in utilising the principle devised by Pacinotti, which was as follows: In all the early forms of dynamos and motors there were a number of magnets and a number of coils of wire, the magnets moving relatively to the coils, or the coils relatively to the magnets, as you see in this rather old specimen of alternate-current dynamo. To produce magnetism by a large number of little magnets is not economical, and Pacinotti's device consisted in arranging a number of coils round a ring in the way shown in the large wooden model (model shown) so that they could all be acted on by one large magnet. Instead of frittering away his magnetism, Pacinotti showed how it could be concentrated, and thus he led the way to dynamos and motors becoming commercial machines. Pacinotti's science, engineered by Gramme, not only made electric lighting commercially possible, but led to electricity being used as a valuable motive power. It was in their work that the electric transmission of power in its modern sense sprang into existence.

Quite recently an improvement in the same direction has been introduced into alternate current dynamos by Mr. W. N. Mordey, for he has replaced the many magnets of the ordinary alternate current dynamos with one large magnet, and so, with his alternator, weighing 41cwt., which you see in this hall, he has succeeded in obtaining, at a speed of 650 revolutions per minute, at output of 53·6 h.p., with a high efficiency.

It may be convenient to mention at this stage the very valuable work that has been done by the Doctors Hopkinson, Mr. Crompton, Mr. Kapp, and others in the improving dynamos and motors by applying scientific principles in the construction of these machines. Were I lecturing on dynamos and motors instead of on the electric transmission of power I would explain to you how by putting more iron into the rotating armature, as it is called, and less wire on it, by shortening the stationary magnet, and, generally, by concentrating the magnetic action, these constructors have raised the commercial efficiency of these machines to actually as high as between 93 and 94 per cent.; further, how, by recognising the force of the general principles laid down by Prof. Perry and myself as to the difference that should exist in the construction of a motor and a dynamo, Messrs. Immisch have succeeded in constructing strong durable electro-motors weighing not more than 62lb. per effective horse-power developed.

The subject is so entrancing to me, the results commercially so important, that I am strongly tempted to branch off, but the inexorable clock warns me that I must concentrate my remarks, as they have concentrated the magnetic action.

Eighty-seven and a half per cent. of the power put into an Edison-Hopkinson dynamo has actually been given out by the motor spindle when 50 h.p. was being transmitted. How does this compare with the *combined* efficiences of an air-pump and an air-motor, or of a water-pump and a water-motor? I understand that in either of these cases 60 per cent. is considered a very satisfactory result. As far, then, as the terminal losses are concerned, electric transmission of power is certainly superior to air or water transmission.

The next point to consider is the loss of power on the road between the dynamo at the one end and the motor at the other. This problem was, perhaps, seriously attacked for the first time in the discussion of a paper read by Messrs. Higgs and Brittle at the Institution of Civil Engineers in 1878, and that problem was considered in some detail theoretically and experimentally at the lecture I gave during the meeting of the British Association in Sheffield in the following year. It was then shown that since the power developed by the generator and motor depended on the product of the current into the electric pressure, while the loss when power was transmitted through a given wire depended on the square of the current, and was independent of the electric pressure, the economical transmission of power by electricity on a large scale depended on the use of a very large electric pressure and a small current, just as the economic transmission of much power by water depended on the use of a very large water pressure and a small flow of water. At that time it was not thought possible to construct a small dynamo to develop a very large electric pressure, or potential difference, as it is technically called, and, therefore, it was proposed to join up many dynamos in series at the one end, and many lamps or electric motors in series at the other, and to transmit the power by a very small current, which passed through all the dynamos and all the lamps in succession one after the other.

You have an example to-night of the realisation of this principle in the 15 arc lamps that are all in series outside this drill-hall, and are worked with a small current of only 6·8 amperes as

Digitized by Google

indicated in the wall diagram, and a further example in the thirty arc lamps at the Bath Flower Show, which are also all worked in series with the small current passing through them; but it is known now how to produce a large potential difference with a single dynamo so that a single Thomson-Houston dynamo belonging to Messrs. Laing, Wharton and Down supplies the current for each of the two circuits.

The electric pressure, or potential difference, between the terminals of any arc lamp is not high, but it *is* between the main wires near the dynamo as well as between these wires and the ground. How far does this lead to the risk of sparks or unpleasant shocks? That is a point that can be looked at in a variety of ways. First, there is the American view of the matter, which consists in pointing out to people exactly what the danger is (if there be any), and training them to look out for themselves. Let ordinary railway trains, say the Americans, run through the streets, and let horses learn to respect the warning bell. Next, there is the semi-paternal English system, which cripples all attempts at street mechanical locomotion because we are conservative in our use of horses, and horses are conservative in their way of looking at horseless tramcars. Lastly, there is the foreign paternal system which, carried to its limit, would prohibit the eating of dinners because some people have at some time choked themselves, and would render going to bed a penal offence because it is in bed that most people have died.

We laugh a good deal at the rough-and-ready manner adopted on the other side of the Atlantic. The Americans, no doubt, are very ignorant of the difficulties that properly-minded people would meet with; but it is a blissful ignorance where "it is folly to be wise. Every English electrician who has travelled in America comes back fully impressed with their enterprise and their happy-go-lucky success. They have twenty-two electric tramways, carrying some 4,000,000 passengers annually, to our four electric tramways at Portrush, Blackpool, Brighton, and Bessbrook. Why, New York City alone, Mr. Reckenzaun tells me, possesses 300 miles of ordinary tramway track, and Philadelphia City 430 miles, so there is more tramway line in these two cities than in the whole of the United Kingdom put together. Now, there would be no difficulty in proving to anyone unfamiliar with railway travelling that to go at fifty miles an hour round a curve with only a bit of iron rail between him and eternity, would be far too risky to be even contemplated. And yet we do go in express trains, and even eighty miles an hour is beginning to be considered not to put too great a demand on the funds of life-insurance companies. The American plan of basing a conclusion on experience rather than on anticipation is not a bad one, and if we follow that plan, then taking into account that there are 75,000 arc lights alight every night on the Thomson-Houston high-potential circuits throughout the world, and the comparatively small number of people that have suffered in consequence (not a single person, I am assured, outside the company's staff), we are compelled to conclude that high potential now is what thirty miles an hour was half a century ago—uncanny rather than dangerous.

But it is possible to use a very large potential difference between the main wires by means of which the electric power is economically conveyed a considerable distance, and transformed into a very small potential difference in the houses where it is utilised. An electric transformer is equivalent to a lever, or wheel and axle, or any other of the so-called mechanical powers. You know that a large weight moving through space distance can raise a small weight through a large distance. There is no gain in the amount of work, but only a transformation of the way in which the work is done. A large weight moving through a small distance in analogous with a high potential difference and a small current, while a small weight moving through a large distance is analogous with a small potential difference and a large current, and an electric transformer is for the purpose of effecting the transformation with as little loss as possible, so that what is lost in potential difference may be all gained in current. Electrical transformation may be effected by (1) alternate current transformers, (2) motor-dynamos, (3) accumulators or secondary batteries, and (4) direct current transformers.

Of these apparatus the oldest by far is the alternate current transformer, as it is merely the development of the classical apparatus invented by Faraday in 1831, and familiar to many of you as the Ruhmkorff or induction coil. A combination of a motor and dynamo was suggested by Gramme in 1874. Accumulators are the outcome of Planté's work, while direct current transformers are quite modern and not yet out of the experimental stage.

After studying the literature of this subject it appears, as far as I have been able to judge, that the first definite proposal to use a high potential difference in the street mains and transform down to a low potential difference in the houses was made in the lecture given by me at the meeting of the British Association in Sheffield in 1879, on which occasion I explained and showed in action the motor-dynamo principle suggested by Prof. Perry and myself. The apparatus on the platform is not unlike that shown on the former occasion; an Immisch motor working at 500 volts, and with a current of 6·8 amperes, is geared direct to a Victoria brush dynamo giving five times that current, and we will now use this larger current to produce an electric fire (experiment shown). Messrs. Paris and Scott have combined the motor and dynamo into one machine, which they have kindly lent me, and by means of which we are now transforming about 700 volts and 6·8 amperes into 100 volts, and about 40 amperes used to light that group of incandescent lamps and work these motors (experiment shown).

Lastly, here is a working illustration of the double transformation proposed by MM. Deprez and Carpentier in 1881, by means of which, while the potential difference between the mains may be 2,000 or 10,000 volts if you like, not merely is the potential difference in the house so low that you could hardly feel anything if you touched the wires, but, in addition, there is the same security against shocks in the dynamo-room. This alternate current machine is producing about 50 volts, which is transformed up to 2,000 volts by means of this transformer. At the other end of the platform by means of a similar transformer the 2,000 volts is transformed down again to 50 volts employed to light that cluster of low voltage incandescent lamps (experiment shown). I have to thank the Anglo-American Brush Company for the loan of the apparatus.

(To be continued.)

CITY NOTES.

Brazilian Submarine Telegraph Company.—The traffic receipts of the Brazilian Submarine Telegraph Company, Limited, for the week ended September 7 amounted to £4,863.

Western and Brazilian Telegraph Company.—The traffic receipts of the Western and Brazilian Telegraph Company for the past week, after deducting the fifth of the gross receipts payable to the London Platino-Brazilian Telegraph Company, were £4,011.

Great Northern Telegraph Company.—The Great Northern Telegraph Company's receipts for the month of August were £23,200, making a total from January 1 of £179,200, against £174,120 for the same period of 1887 and £169,960 in 1886.

Cuba Submarine Telegraph Company.—The number of messages passing over the lines of the Cuba Submarine Telegraph Company during August was 3,507, estimated to produce £2,800, against 2,983 messages, producing £2,280, in the corresponding month. The receipts for May, estimated at £3,300, realised £3,337.

Companies of the Month.—The following electrical companies have been registered during the past month:—

Barnet and District Electric Supply Company, £10 and £1 shares	£5,000
Bedford Electric Light Company, £1 shares	15,000
Electrical Accumulator Association, £10 shares	10,000
Lineff Electric Traction and Lighting Syndicate, £1 shares	10,000
Laurence, Paris and Scott, £10 shares	30,000
Rees' Miners' Patent Safety Electric Lamp Company, £5 shares	50,000

Manchester Edison-Swan Company. — The annual report of the Directors of the Manchester Edison-Swan Company, Limited, presented to the shareholders at their last meeting, states that the net profit, including last year's balance, amounts to £1,781. 15s. 3d., which it is proposed to appropriate as follows: To payment of dividend at 5 per cent. per annum, £1,000; to reserve fund, £500; balance to be carried forward, £281. 15s. 3d.; total, £1,781. 15s. 3d. In accordance with the special resolutions passed on the 5th September, 1887, and confirmed on the 3rd October, 1887, the name of the company has been changed from the Manchester and District Edison Electric Light Company to the Manchester Edison-Swan Company, Limited, and a reduction of the capital has been effected by canceling capital which has been lost, to the extent of £1 per share upon each of the 20,000 A shares issued, and by reducing the nominal amount of all the A shares in the company's capital from £10 to £9 per share. The company's stock and plant have now been depreciated to their present market value, and all losses written off, thus leaving the assets of the company in a sound condition, besides enabling the Directors to place £809. 18s. to a depreciation fund for future contingencies.

PROVISIONAL PATENTS, 1888.

SEPTEMBER 1.

12,592. **An improved means or method of attaching incandescent electric lights to gas brackets or other gas fittings.** Claude Hamilton, 17, Hope-street, Glasgow.

12,593. **Improvements in recording and reproducing sounds, and in means applicable therefor.** George Edward Gouraud, 191, Fleet-street, London, E.C. (Thomas Alva Edison, United States.)

12,594. **Improvements in phonographs.** George Edward Gouraud, 191, Fleet-street, London, E.C. (Thomas Alva Edison, United States.)

12,609. **Improvements in or relating to electrical locks.** William Phillips Thompson, 6, Lord-street, Liverpool. (Ernest Lémonon, France.)

12,620. **Electric secondary battery plates.** Charles Marson, 5, East Terrace, Queen's-road, Battersea, Surrey.

Digitized by Google

SEPTEMBER 3.

12,703. **An improved voltaic battery.** George Thomas Jolland, 54, Fleet-street, London, E.C.

12,705. **Improvements in apparatus for the transmission of power.** Otto Krell, 323, High Holborn, Middlesex.

12,706. **Improvements in storage battery plates.** William Phillips Thompson, 6, Lord-street, Liverpool. (Charles David Paige Gibson, United States.) (Complete specification.)

SEPTEMBER 4.

12,727. **The electric break appliance.** G. Stibbe, acting for Edouard Dubied and Co., Convet, Suisse.

12,740. **Improved apparatus for electrically indicating variations of water level in rivers, aqueducts, mines and the like.** Wallace Fairweather, 62, St. Vincent-street, Glasgow. (Heinrich Christian Spohr, Germany.)

12,754. **Improvements relating to electric bells and to indicating apparatus for use in connection therewith.** Henry Harris Lake, 45, Southampton-buildings, London. (William Humans, United States.) (Complete specification.)

12,759. **An electric-meter or apparatus for recording the passage or consumption of electricity.** Francis Teague, Crown-yard, Stanhope-street, Euston-road, N.W.

12,761. **Improvements in dynamo electric machines.** Addison G. Waterhouse, 321, High Holborn, W.C. (Complete specification.)

12,767. **Improvements in dynamo-electric machines.** William Harding Scott, 64, Hall-road, Lakenham, Norwich.

12,798. **Improved electrical sounding apparatus.** Pedro Vigil and Juan N. Revueltas, 53, Chancery-lane, London.

SEPTEMBER 5.

12,817. **Immediately stopping a steam engine by means of electricity from a distance; may be called "The electric engine stopper."** Edward Dixon, Princess-avenue, Hull.

12,828. **Improvements in electric incandescent lamps.** Félix D'Arc, 57, Chancery-lane, London.

12,832. **Improvements in conductors for armatures of dynamo electric machines.** Frederik Vilhelm Andersen, 3, Elm-court, Temple, London, E.C.

12,856. **Improved apparatus for converting electrical currents.** Carl Zipernowsky and Max Deri, 28, Southampton-buildings, Chancery-lane, London, W.C.

12,858. **Improvements in the distribution of electrical energy.** Carl Zipernowsky and Max Deri, 28, Southampton-buildings, Chancery-lane, London, W.C.

SEPTEMBER 6.

12,887. **An improvement in voltaic cells.** Robert Henelade Courtenay, 78, Wool-exchange, Coleman-street, London, E.C.

12,907. **Improvements in dynamo electric machines.** Thomas Parker and William Lowrie, 433, Strand, London, W.C.

COMPLETE SPECIFICATIONS ACCEPTED.

SEPTEMBER 14, 1887.

12,437. **Improvements in and connected with dynamo electric machines.** Rookes Evelyn Bell Crompton and James Swinburne, Arc Works, Chelmsford.

SEPTEMBER 21, 1887.

12,830. **An improved regulating device for use in electric arc lamps and for other purposes.** William Robert Lake, 45, Southampton-buildings, London. (Otto Heinrich Louis Lindemann, Germany.)

SEPTEMBER 23, 1887.

12,924. **Improvements in the manufacture of incandescent electric lamps and of carbon rods therefor.** Geminiano Zanni, 45, Southampton-buildings, London.

NOVEMBER 8, 1887.

18,030. **Improvements in thermo-electric batteries.** Louis Charles Emile Lebiez and Paul Louis Verchére, 55 and 56, Chancery-lane, London. (Received 5th March, 1888, antedated 8th November, A.D. 1887. Under International Convention.)

NOVEMBER 17, 1887.

15,754. **Improvements in the electrolytes of secondary voltaic batteries.** William Joseph Starkey Barber-Starkey, 70, Market-street, Manchester.

FEBRUARY 20, 1888.

2516. **A new or improved apparatus or inductometer for measuring the intensity of a magnetic field.** George Mist, 46, Lincoln's-inn-fields, London, W.C.

JULY 10, 1888.

9991. **Improvements in magneto-electric apparatus.** William Robert Lake, 45, Southampton-buildings, London, W.C. (William Heemans, United States.)

JULY 28, 1888.

10,954. **Improvements in or connected with dynamo electric machines.** Ernest Heinrich Geist, 433, Strand, London.

AUGUST 4, 1887.

11,338. **Improvements in telephone line circuits.** Léon Kelner, 24, Southampton-buildings, London, W.C.

SPECIFICATIONS PUBLISHED.

1887.

10,611. **Electrical batteries.** R. P. Milburn. 6d.

10,833. **Electric lamps.** F. R. Boardman. 8d.

10,838. **Electrical switches.** F. L. Rawson and W. White. 8d.

10,952. **Dynamo electric machines, &c.** L. Anspach and L. Gerard. 8d.

11,802. **Incandescent lamps.** A. Shippey. 8d.

12,203. **Dynamo electric machines.** T. L. Hemming. 8d.

13,320. **Electric regulators.** J. G. Statter and S. L. Brunton. 8d.

13,510. **Microphones.** W. Genest. 8d.

13,558. **Casings for electrical conductors, &c.** P. Everitt and P. R. Allen. 8d.

14,024. **Secondary batteries.** N. De Bernados. 8d.

14,029. **Electrical tramways and railways.** F. C. Allsop. 11d.

1644. **Recording and reproducing sounds.** T. A. Edison. (Third edition.) 1s. 1d.

1888.

5681. **Electrical switches.** C. S. Snell. 8d.

9981. **Recording and reproducing sounds.** J. Y. Johnson (The Volta Graphophone Co.). 8d.

NOTES.

Kansas Electric Railway.—The Thomson-Houston Company are constructing a long line of electric road at Kansas City on their now well-tried system.

Algeria.—The municipality of Orleansville, Algeria, has put up to tender the installation and carrying on of a central station for the public and private lighting of that town.

Birkenshaw.—The ratepayers have held a meeting to consider the gas question, being greatly dissatisfied with the present light at Birkenshaw. The present public lights are to be discontinued.

Kensington and Knightsbridge.—The Kensington Court Electric Lighting Company has changed its name to "Kensington and Knightsbridge," and is now extending its operations into the Knightsbridge district.

Crude Petroleum.—Crude petroleum is extending its use as fuel. A barrel of Lima oil, which cannot be refined like other oil, is said to be equal to a ton of fuel. At Lima it is used to supply power for an electric railway.

Heanor.—A committee has been formed to consider the purchase of the local gas works, and to consider the question of electric light. The chairman thought that in a short time electric light would be within easy distance.

Burning the Eyes.—The acute pain in the eyes sometimes experienced from looking at arc lights is thought to be often due to the smoke which comes from the carbons. The copper coating seems to give off a poisonous vapour which affects the sight.

Errata.—In Lord Rayleigh's paper, given on pp. 227-8, the following corrections should be made: First line read *Roiti* instead of *Roite;* and end of first paragraph read *interference* instead of *influence;* in the note marked * p. 228, read *five*, instead of *fine.*

Common Sense Rule.—Mr. S. S. Wheeler recommends this rule for the regulation of arc lights, that "an arc lamp within the reach of any man's umbrella is hung too low," a common sense suggestion which should recommend itself everywhere.

Cure for Writer's Cramp.—A few gentle shocks from a small coil are said to cure the cramp of the muscles which follow continual use of the pen. The battery and coil is a fixture in the office equipments of a recording office of the Superior Court, Baltimore.

The Otto Gas Engine.—It is announced that M. Otto, the inventor of the gas-engine, has just constructed a new machine which automatically prepares its own gas by means of the Dowson apparatus. The new model is of 8 h.p., and only consumes 2lb. of coal per horse-power hour.

Steering the Dog-Cart.—The Sultan's dog-cart steers the other way to a bicycle, by reason of its geared wheel, as our contemporary's representative found to his cost last week, when he ran the vehicle through the rails, over the benches, and into the bank, and nearly spoilt the whole show.

Long-distance Telephony.—The Postal and Telegraph Administration of Austria have commenced the construction of a long-distance telephone line between Vienna and Prague. The telephone line between Alexandria and Cairo will shortly be completed, the last of the apparatus having arrived.

Paris.—The Gymnase Theatre has been lighted with electric light. In this installation 56 Schenck-Farbaky accumulators are used in two batteries, which together give an output of 320 amperes. These are charged by two Thury dynamos. The installation comprises 883 Khotinsky incandescent lamps.

Noise from Commutators.—The noise of the brushes on the commutator is sometimes uncomfortably noticeable. If this is ever the case, let the commutator be occasionally slightly greased with vaseline, and a box with wadding or slag wool, under a lining, be fitted over the brushes. This will reduce the noise to a minimum.

Free Telephony.—By the courtesy of the directors of the Western Counties and South Wales Telephone Company, the whole of the section-rooms during the Bath meeting of the British Association were telephonically connected, for free use of the visitors, with the reception-room and with all important places in the neighbourhood.

Physical Society, Glasgow.—The 1888–9 session of the Physical Society of the Glasgow University commenced on September 14, when the president, Mr. M. Maclean, M.A., delivered his address on "Electric Hypotheses." The next meeting is on September 28, when a paper, on "The Electric Fishes," will be read by Prof. M'Kendrick, F.R.S.

The May Island Electric Light.—Captain Boldt, of the Danish mail steamer "Thyra," which arrived at Granton on Tuesday afternoon from Copenhagen, reports having sighted the May Island light, Edinburgh, at half-past three o'clock in the morning, distant sixty-one nautical miles. This is the highest recorded distance at which the reflection of the light has been observed.

Aberdeen.—The Aberdeen *Herald and Weekly Free Press* has just moved into large new offices. The whole establishment has been supplied with the electric light, which is now coming very rapidly into use in establishments where much artificial light is required. The dynamo is driven by a powerful engine supplied by the well-known firm of Marshall, Sons and Co., Gainsborough.

Electric Omnibus.—It is not generally known yet, but we learn that there is running in the streets of London in the early hours—from three to five nearly every day of the week—an electric omnibus, for the purpose of testing the practicability of this invention in the City streets. The route has been by Hyde Park, Oxford-street, Holborn, Fetter-lane, Strand, to the Hotel Metropole. Further particulars will be forthcoming shortly.

Lighting in Derby.—Messrs. Rowbotham and Godwin, Iron Gate Works, Derby, write to say that two years ago they fixed 40 incandescent lamps and one 2,000 c.p. arc lamp for Messrs. W. D. Borraill and Co., and have also fitted 400 incandescent lamps for Messrs. W. Rickard and Co., electric wire manufacturers, so that they are the first firm to introduce the electric light into Derby. They are at present lighting up the premises of Mr. T. E. Yeomans, of Derby, and are among those tendering for the public lighting of the streets of that town.

The Sun Motor.—In the latest form of Captain John Ericson's perfected sun motor, recently described in *Nature*, flat surfaces and parallel rays for purposes of reflection are adopted for utilising the sun's heat instead of curved surfaces and converging rays. He states that a surface of reflecting mirrors of 100 square feet presented at right

Digitized by Google

angles to the sun (at noon) in the latitude of New York, during the summer, develops a mechanical energy reaching 1,850,000 foot pounds per hour, and asserts that the sun power can be made steady and constant.

Madrid.—Madrid is shortly to have a large public central station for supply of electric light. A company, under the name of "La Luz Natural," has been formed by local capitalists, and the installation, consisting of 1,000 h.p., is already in progress. The wires will be overhead. The charge is fixed at a rate equal to ½d. per lamp-hour of 16 c.p., the replacement of lamps being at the charge of the consumer. The greater number of the theatres in Madrid have arranged to be connected with this source of supply, the Theatre Royal alone being excepted.

Cheltenham.—The borough surveyor has reported that the following sites might be utilised for the erection of the necessary buildings and apparatus for an electric light installation at Cheltenham: 1, water works pumping station and land in Sandford Mead; 2, land and buildings at Barrett's Mill; 3, land at the Central Depot; 4, the south-west portion of the Cattle Market; or 5, land adjoining the site of the proposed refuse destructor. The sites No. 3 and 5 would have the advantage of railway communication. Of these sites the committee consider those of Barrett's Mill and the Central Depot the most suitable.

Lowrie-Hall System.—The fact announced by us a short while ago that Hammond and Co. are completing a central station plant, to be sent to America, naturally excited some comment upon that side of the ocean. We add a few further particulars. The plant is for a town in the Argentine Republic, South America, and consists of alternate-current dynamos and transformers on the Lowrie-Hall system, fitted with their automatic E.M.F. regulator for alternate currents, regulating to within one volt, together with a complete system of switchboards and special meters for measuring the currents. The plant will be despatched in a few weeks.

Electric Photography.—It is stated that the latest and strangest case of the uses of applied science recently occurred near Perigeux, France, where five persons were imprisoned by the caving-in of a quarry wall, and there was no means at hand to rescue them. To find out where they were, a shaft 12in. in diameter was bored, down which was slid a tube, near the end of which was a small camera surrounded by a battery of electric lights. With this apparatus a number of negatives were taken, and the effect of the disaster shown, even to the faces of two corpses. It was thus known that the men were dead, and that efforts to succour them would be useless.

Grand Theatre, Liverpool.—A fine theatre installation is being carried out by Messrs. A. H. Fletcher and Co., of Liverpool, at the Grand Theatre in that town. The installation will be worked at present by a 50-h.p. Otto gas-engine in the basement. The dynamos are supplied by Messrs. J. G. Statter and Co. The theatre will be lighted throughout with incandescent lamps varying from 1,000 to 16-c.p. at 100 volts. The limelight will be replaced by an arc light projector by Messrs. Statter, and arrangements are made for raising and lowering the brilliancy of the light for stage usage. Ventilating fans driven by small electromotors will be placed in the auditorium and refreshment-rooms.

Municipal Lighting of Paris.—The Municipal Council of Paris are intending to hold three open competitions for the construction and installation of (1) dynamos and apparatus, (2) engines, and (3) boilers. Plans and prospectuses are to be seen at the Hotel de Ville (Direction des Travaux, 2 division, 3 bureau), Paris. Competitors must send in, before the 10th of October next, to "M. le directeur de la Voie publique et des Promenades, avenue Victoria 4," certificates stating the capabilities and giving particulars of similar work already undertaken. Two committees will meet at the Hotel de Ville on 25th October to deal with dynamos and apparatus, and on 26th October with engines and boilers.

Electric Sugar.—A meeting of the shareholders of the Electric Sugar Refining Company was held in Liverpool on Sept. 17th, to hear the report of Mr. R. Roberts, of Birmingham, who was delegated to visit the factory at New York. He stated that the trial had proved in every way satisfactory. There were four granulators, and with one of these at work 150 barrels had been filled with refined sugar in an hour and ten minutes. In a few weeks the remaining granulators would be working, and the factory turning out sugar at the rate of 5,000 barrels a day. The shareholders present expressed themselves satisfied with the progress made. After their recent phenomenal advance from £20 to over £100 a share, Electric Sugars have settled down between 85 and 90. The dealings in them continue to be very active, and the Liverpool papers now quote the price every day.

Wolverhampton.—The councillors of Wolverhampton, being dissatisfied with the gas, and having Messrs. Elwell-Parker on the spot, have asked these gentlemen their opinion with regard to lighting the town with electricity. They advise the corporation that they cannot at present recommend the lighting of the streets alone, owing to the length of the leads necessary, and the consequent labour in laying down. But Messrs. Elwell-Parker are of opinion that if street lighting were combined with domestic lighting, a 40,000 lamp installation could successfully compete with gas in Wolverhampton. After a discussion the gas contract was renewed with certain restrictions, but Mr. Alderman Gibbons did not believe that the town would ever secure relief until a competition was started in the shape of electric lighting, and thought the corporation should start their own plant.

Mining Lamps.—In the paper of Mr. Watts, read at the British Association, reference was made to a miners' lamp issued by the Portable Electric Lamp and Power Syndicate, and we are able to give the following further information about the lamp. The 2-cell miners' lamp gives a light for eighteen hours equivalent to one candle, and weighing four-and-a-half pounds.

Average E.M.F. (in closed circuit for 12 hours)	3·75 volts.
Current through lamp	·323 ampere.
Power expended in external circuit	1·211 watts.
Capacity of negative element	7 amp.-hours.
Electrolyte used is dilute sulphuric acid.	
Specific gravity of the electrolyte	1·170
Weight of elements complete	1lb. 3oz.
„ negative element (lithanode)	6oz.
„ positive element (spongy lead)	2½oz.
Total height	8 inches.
Total diameter	4 inches.

Electro-Medical Apparatus.—Mr. K. Schall, of 55, Wigmore-street, W., sends us a very complete and well got-up little catalogue of all kinds of medical apparatus in which electricity is used. These include medical batteries for exciting Ruhmkorff coils, for the electrolysis of tuber-

Digitized by Google

culous growths, for cauterisation, for supply of small electric lamps to be carried on the forehead in operations, and for illuminations of the cavities. It also includes numerous electrodes for the electric treatment of various parts of the body, designed by Dr. Apostoli, Prof. Erb, Dr. Boudet, Dr. Duchène, and others, also induction coils by Dr. Dubois-Reymond, Dr. Hedinger's large plunge battery, requiring filling only once every four to 12 months, static induction machines for what is called Franklinisation, and for the production of ozone. The list also includes galvanometers, rheostats, and other apparatus likely to be required by medical men.

Burning out the Telephones.—There seems a strange fatality about the telephone systems in some parts of America. We constantly notice reports in the transatlantic journals of thunderstorms playing mischief with the telephone wires, breaking them down and burning out the drops in the exchange. Two cases recently in Arkansas are of this nature, and another in which an old unused telephone set fire to a house. At St. Joseph, Missouri, over three hundred telephones were burnt out. New Orleans has also just suffered from a storm, the telephone and telegraph wires getting crossed with the electric light wires, causing destruction in all directions. The mischief seems sometimes to arise from the lightning, and often from crossing of the electric light wires, but it certainly seems strange that proper precautions are not taken by use of lightning arresters to guard against lightning, and by fuses, if necessary, to guard against accidental heavy currents.

Window Lighting.—Here is a tip for those who have to do with shop window lighting where incandescent lamps are used throughout. A shopkeeper had his window lighted with 16 c.p. incandescent lamps, but the effect was not much better than ordinary gas, and by far the greater proportion of the passers-by would not even notice that he had the electric light. "What!" he asked himself, "to have all the expense of the electric light and none of the credit? This will never do." He consulted an electrical friend, who gave him the following advice: "Your E.M.F. is 100, your lamps are 100 volt lamps; continue to use these in the shop itself, but in the window, where you want a more brilliant and attractive light, *use lower voltage lamps*—96, 90, or even 85. Never mind if they burn up a little faster—as they will—the extra expense will well repay itself in advertisement." This advice was followed, and from being a dull shop it is now the most brilliantly lighted, and a crowd of admiring sight-seekers constantly stop, attracted by the beauty and clearness of the lamps.

New Catalogue.—We have received from Messrs. B. Verity and Sons their new catalogue of electric fittings, which contains a very large number of illustrations of electroliers, brackets, shades, and other fittings designed specially to be used with incandescent lighting. Messrs. B. Verity and Sons have had a very large experience, and may therefore be supposed to have fairly gauged the public taste in this direction. They use for the construction of these fittings polished copper, copper and brass, and copper and silver work, and we understand that so great has been their success in this direction that they have been compelled to fit up a new factory, to be especially devoted to electric lighting work. The illustrations in this catalogue have been prepared by the Phototype Co., and the whole catalogue is very tastefully and handsomely got up. With regard to the designs themselves we believe that most, if not all, are due to Mr. S. Crichton Hannah, an artist who is rapidly taking a prominent place in the country, and who has exhibited at the Royal Academy the last two years.

The Whitehall Station.—Whitehall will be "up" early next week for the laying of the mains of the first large underground system of distributing electricity in London. Whitehall, being adjacent to Charing Cross and extending to Westminster, is the actual centre of London, and the metropolis can at any rate congratulate itself that public supply of electric lighting on a commercial scale has at last been inaugurated. The station itself has been in progress of installation by Messrs. Crompton and Co., of Chelmsford, for some time for the Whitehall Court Company, who have lately sold out to the recently-formed Metropolitan Electric Supply Company, who are shortly intending to undertake the public supply on an extended scale. The work of manufacture and laying the main cables is undertaken by Messrs. Callender and Co., who have adopted special methods of manufacture for their heavy electric light cables, and special methods of laying the same underground. It is expected that the supply of electric current for lighting purposes in this district will be ready for the ensuing season.

Glasgow Municipal Buildings.—The Committee of Glasgow Town Council, which has charge of the electric lighting arrangements of the new municipal buildings, having opened and examined the designs of electroliers, gasaliers, and brackets which had been sent in, have selected the following: (1) Design by Messrs. B. Verity and Sons, London, per Messrs. John Finlay and Co., Glasgow, of electric pendant for the corridors, provided it is, or is made, large enough for four electric lights; the price is £13. 10s. It will be for the architect to say how many of these will be required. (2) Design by Messrs. B. Verity and Sons, London, for four gasaliers, one for each of the committee rooms; the price is £30 each. (3) Design by Messrs. B. Verity and Sons, London, for six 10-light electroliers for the salons, subject to the makers agreeing, without extra charge, to alter the design as now suggested, and the architect was instructed to see Messrs. Verity as to this—the price is £45 each; and (4) design by Messrs. Winfields, Limited, London and Birmingham, for two gasaliers with four two-light arms, one for the Lord Provost's room and one for the library—the price is £24. 10s. each.

Liverpool Central Lighting.—A most ambitious scheme, upon a scale commensurate with the importance of the town and the acknowledged advantages of the incandescent light, is now well in progress in Liverpool. The Liverpool Electric Light Company, although one of the largest and most prosperous in this country, has seldom been heard of, its policy evidently being to act much and speak little. Growing gradually from small beginnings, this company has developed into larger and larger scope, and has at last begun work upon a central station scheme for supply of the best part of the town of Liverpool. A special Act has been granted with reference to powers for taking up streets and public supply, the permission has been obtained from and plans approved by the Board of Trade and the city engineers, and the cables are rapidly being made for the installation. The district is one of the busiest parts of the town, comprising Dale-street, Water-street, Brunswick-street, Chapel-street, James-street, Victoria-street, &c., and extending to Lime-street station. The cables are being specially manufactured by Messrs. Callender and Co., 101, Leadenhall-street, with special methods of laying underground. Double mains

Digitized by Google

will be laid on both sides of each street. The number of lights at present provided for number eight to ten thousand, but may probably be extended very shortly up to 50,000.

Aluminium.—It will have been noticed by many of our readers that Mr. Crompton, in his paper at the British Association, referred to Mr. W. J. Keep's work in America on "The Influence of Aluminium upon Cast Iron." In the current number of the *Journal* of the Franklin Institute is a paper by Messrs. Keep, Mabery, and Vorce, upon this subject, as read before the American Association for the Advancement of Science, at Cleveland. The subject is considered under twelve headings, and the whole paper will be of exceedingly great interest to all makers of cast iron, and should have a marked effect upon the requirements of aluminium alloys, and so indirectly upon the construction of large dynamos. Briefly, we may say that, by using aluminium in the casting, greater strength and solidity is obtained, and that the influence seems to be exerted in a greater degree by remelting. Another noticeable feature is, that aluminium causes the carbon to assume the graphitic form on the instant of solidifying, and, therefore, the sudden abstraction of heat does not cause chill. This effect of aluminium, therefore, is to give a uniform grain for thick and thin castings, and not allow the coldness of the mould to affect the grain. The paper concludes with the following sentence: "This hurried presentation of the remarkable effects of aluminium upon cast iron will give an idea of the great benefit which is now promised to the iron founder by the rapidly falling price of aluminium as cheapened by the electric furnace."

Search Lights for War Purposes.—The German military authorities, says *Industries*, have made some interesting experiments in night attack with the aid of the electric light. The plant used consisted of an 18 h.p. portable steam-engine, carrying a dynamo and search lamp. The novelty of the experiment consisted in using the beam of light, not direct, but as reflected from a second mirror, placed about 200 yards distant from the lamp, so that the enemy should remain in ignorance of the exact position of the electric lighting plant itself. The projector is fitted with an electro-motor, by which it may be set to any desired angle, the current being supplied by two cables from the dynamo, where the movement of the projector is controlled. Thus it becomes unnecessary to place a man close to the projector, a point which would obviously be one of great danger. The cone of light from the second projector rendered everything within a radius of 4,000 yards clearly visible. It was also found that the small quantity of diffused light in the vicinity of the lamp greatly facilitated exact aim. A party of riflemen were placed near the lamp, so that the sights of the rifles were illuminated by the diffused light, and in firing upon targets 400 yards distant, nine shots out of every ten were hits, whereas, with another party placed further back, and wholly in the dark, the shooting was far less accurate. The intensity of the light prevents the enemy from taking exact aim at the engine or any other object which is in comparative darkness.

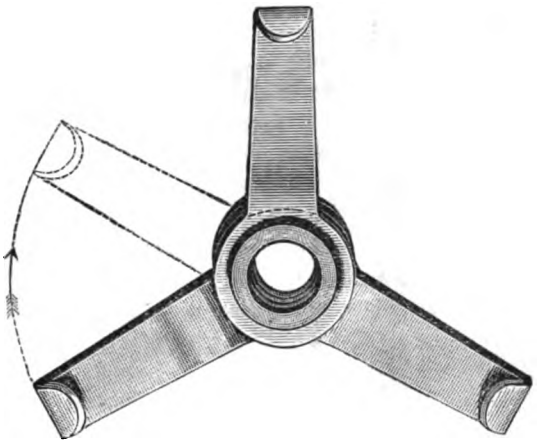
New York Electric Light Convention.—Two important electrical conventions have just been held at New York, the first an electric light convention, and the second a telephone convention. A great deal of interesting exchange of experiences took place, and several valuable papers were read, some of which, being of general interest, we may take occasion to reproduce later on. Mayor Hewitt, of the Board of Electrical Control, stated that at first, believing electric light was a source of danger, he had investigated the matter, but found that, on the whole, they had infinitely more accidents with horses, with steam-engines, even in the building of houses, in the year than with electric light, and the results seem to show that it was positively less dangerous in proportion to any other useful agency at work in the city. A resolution was passed by the convention that they deplored the effort of rival interests to educate the public to a distrust of high potential currents, and that it was their conviction that there is no difference in the danger attending the use of continuous or alternating currents, and that both may be so transformed before being used as to render them perfectly harmless and practicable means of distributing electric power for cities. Papers were read by Mr. S. S. Wheeler on "The Overhead and Underground Wires in New York," on "Disruptive Discharges in Underground Cables," by E. G. Acheson; a description of "The Chenoweth Conduit," by A. C. Chenoweth; and a valuable paper upon the "Basis from which to Calculate the Charges for Electric Motor Service," by H. L. Lufkin. At the telephone convention several papers were read upon the "Dynamo Current Interferences with Telephone Service," and its prevention. Good must always accrue from meetings of this scientific and social character of persons in charge of installations and businesses from widely different places, and we are glad to see the meetings have been both thoroughly successful and enjoyable by the visitors.

The Rees Electric Safety Lamp.—The new safety electric lamp, invented by Mr. J. P. Rees, electrical engineer, Trinity-place, Swansea, has recently been inspected by a large number of colliery owners and managers, and others interested in the working of mines. The body of the lamp is composed of a vulcanite case measuring 5¼in. by 5in. by 3in. To the lid is attached a small brass cylinder, and on this cylinder is placed an elongated glass dome ⅛in. thick. In the vulcanite case are four cells in separate compartments, containing a supply of carbon in porous pots, which is connected with zinc in the next compartment by means of a short brass pin, with screws at each end, and placed above the surface of the diluted sulphuric acid, with which a series of cells are filled, the porous pots being filled with a liquid prepared by the inventor. Within the lid is a flat piece of indiarubber covered with paraffin wax, and which prevents the liquids from mixing together, or spilling whilst being carried. Inside a glass dome, at the top, is a bulb with an incandescent lamp, and the space between the bulb and the dome is filled with compressed air, forced from a small hand-pump through a tube, and prevented from escaping by means of a screw. This compressed air forces the bottom of the brass cylinder down, and by this device the circuit is completed. The compressed air may be left in for an indefinite time, and the circuit broken by opening the lid alone. It requires great force to break the glass dome, but should it any time be broken in the course of working, the circuit would be broken at the same time, and the light extinguished before the bulb could possibly break, so that its safety would not even then be diminished, nor can it be tampered with without being extinguished. The light given in the first instance is of 3 c.p., but by means of a number of lenses it is increased in one direction to eight times its intensity. The cost of the lamp is 30s., and it is stated that it can be maintained for ten hours at a cost of 1d.

Digitized by Google

A NEW SHADE OR GLOBE HOLDER.

We illustrate herewith a new shade-holder, designed and manufactured by Messrs. Appleton, Burbey, and Williamson. Instead of gripping the shade or globe by means of screws as in the ordinary holder, the arms in this new design are movable, as shown in one instance by the dotted lines. When the arm is in the position shown by these lines, the shade or globe can be put into place, and the arm being brought back into position safely grips the globe. This



little fitting is very convenient for pendant lamps, the holder being screwed to the centre of the boss, and for electroliers and brackets it is a great improvement on the old form, as there are no screws to work loose or get lost. It is singular that so simple an idea should have waited so long before being put into a practical shape.

CORRESPONDENCE.

"FLATS" ON COMMUTATOR.

To the Editor of The Electrical Engineer.

Sir,—I shall be glad if you will allow me space to explain to "Broad Bent" that it was not my intention to put forward my idea on the cause of "flats" as final; it was merely that I had never seen this cause mentioned before, and that I cannot remember a case incurable by resoldering, out of a considerable number of machines I have tested.

As to the increased resistance of a segment causing a *greater* difference of potential, it seems to me that in the normal state each section will have the same difference. When one is higher in resistance than the others, the total E.M.F. being the same, will not there be a greater difference across the section of highest resistance? The coil will be *carrying* the current, even though inactive in producing E.M.F., except when momentarily short-circuited by the brush. In conclusion, I would say that, as a young electrician myself, I had no intention to contradict or dogmatise, but merely to offer a suggestion which I hoped might be useful.—Yours, &c.,

Derby. T. M. Winstanley Wallis.

CROMPTON'S LARGE DYNAMO.

To the Editor of The Electrical Engineer.

Sir,—I was very much interested in the paper read by Mr. Crompton before the B.A. at Bath; that part of the paper most interesting to those engaged in dynamo manufacture is no doubt where Mr. Crompton gives the details of the big machine constructed by his firm. The first thing that one notices is the very small amount of laminated iron in the armature core, the radial depth of this part of the machine being about the same as in an ordinary 30-unit machine. The enormous mass of solid metal in the centre of the armature, situated in a strong magnetic field, must be the seat of very wasteful eddy currents. Perhaps this is one of the reasons why a fan has been added to the natural cooling properties of the machine. It will also occur to most electricians that the machine being practically series wound, will largely account for the sudden fluctuations of current which were experienced, and which caused so great a strain on the arrangements provided to carry the armature conductors through the resistance of the magnetic field. None of the descriptions of the Cowles' process which I have read mention any electrolytic action of the current, the sole function of which seems to be to raise the matter under treatment to the very high temperature required. In this case one would think that an alternating would be preferable to a continuous current machine, on account of the great reduction in the first cost of the electrical plant, and the reduction of the cost of repairs, as there would be no expensive commutator to renew, &c. Perhaps there is some objection to the employment of an alternating current which at first sight does not appear; however, I venture to offer the suggestion for what it is worth.—Yours, &c. W. H. Eaves.

Coventry, September 18, 1888.

SHALLENBERGER'S ELECTRIC METER.

Some months ago a new application of the alternating current in the production of rotary motion was made known almost simultaneously by two experimenters, Nikola Tesla and Galileo Ferraris, and the subject has attracted general attention from the fact that no commutator or connection of any kind with the armature was required. The principle has been very successfully applied by Mr. Tesla in the production of a practicable motor, which is destined soon to occupy an important place among the growing number of electrical appliances depending upon alternating currents for their operation.

For some time previous to the publication of the results above referred to, Mr. O. B. Shallenberger, electrician of the Westinghouse Electric Company, had been at work on a series of experiments tending in the same direction, the results of which served as a basis for the construction of a meter depending on analogous principles, although applied in a way differing notably from anything described up to the present time by either of the investigators referred to. The meter was already completed in an experimental form at the time when the results of the experiments of Mr. Tesla and Prof. Ferraris were made known, and its thorough practicability was demonstrated, although for legal reasons it was unadvisable to make the fact known at that date.

Notwithstanding the urgent need of a meter wherever electric lighting has been carried on commercially, nothing has presented itself thus far that indicated any decided advance in this direction until the advent of the instrument invented by Prof. Forbes, the great simplicity and beauty of which cannot be gainsaid. The one apparent difficulty in the way of its adoption seems to be its extreme delicacy in the necessarily minute accuracy in its manufacture and adjustment required to obtain satisfactory results.

It has been the desire of Mr. Shallenberger to produce a meter equally simple, but, if possible, more practicable in its nature, and requiring a less degree of skill on the part of the workmen in manufacturing; or in other words, something that could be made and used in a rough and ready way without diminishing its reliability.

This, it is thought, has now been accomplished, although the use of the instrument in its present form is limited to alternating currents. In this connection it may be observed that although a few years ago one of the objections raised against the use of alternating currents was the difficulty in measuring them in a practical way, the fact is that these difficulties have gradually disappeared, until they are less important than in the use of direct currents.

The principle upon which the new meter operates may be understood from the following considerations. If an alternating current be made to traverse a coiled conductor in proximity to two other conductors closed upon themselves, the secondary currents set up in these two conductors will correspond with each other to a greater or less extent in phase, and will be approximately in the same direction at the same instant, but both will differ in phase from the primary or inducing current. An attraction consequently takes place between the two secondary circuits, and if free to move, the conductors carrying these currents will be attracted to each other in a greater or less degree depending on the amount of the primary current and on the displacement of phase between the primary and secondary currents. If one of these conductors be made fixed and the other movable, the motion will evidently be confined to one of the conductors, and if the action can be continued so as to produce the attraction always in the same direction, a continuous rotary motion may be obtained by the inductive action solely, and without any direct communication with the source of current. The discovery of this principle suggested at once the practicability of applying

Digitized by Google

it to the operation of a meter, since it is only necessary to produce a rotary effort or torque in some simple and reliable way, bearing a definite relation to the current that produces it, in order to have a perfectly accurate means for measuring such current.

With this end in view, a number of experiments were made, which it is unnecessary to follow here, presenting a great variety of effects depending in a general way upon the principle referred to, and leading eventually to the form of meter here described.

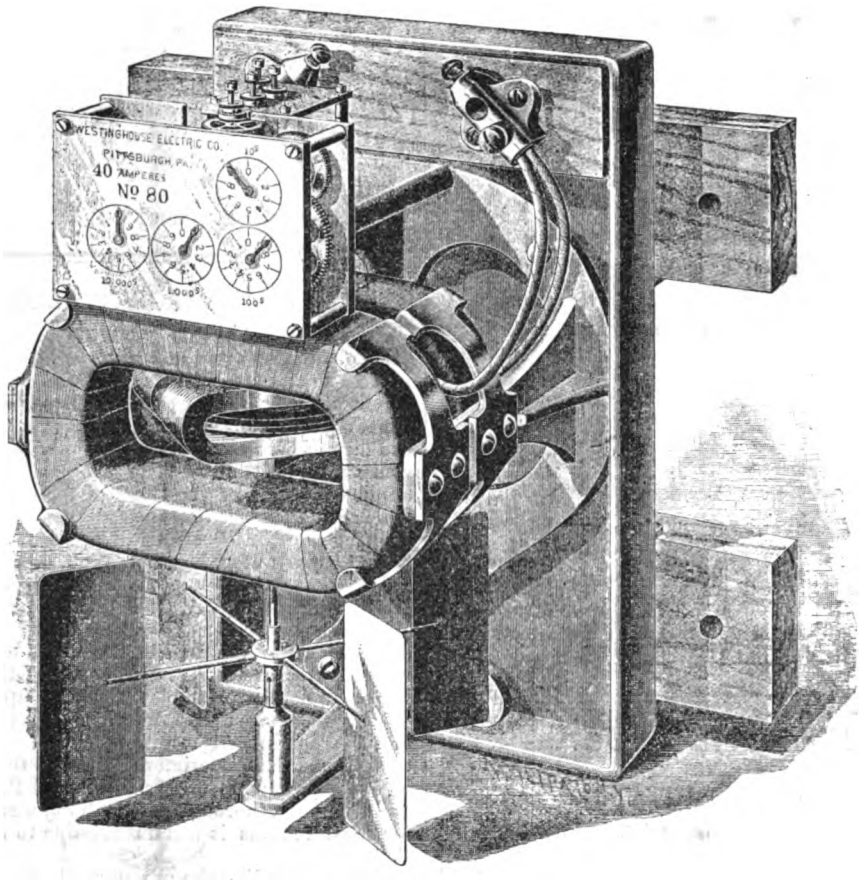


FIGURE 2.—Shallenberger's Meter (case removed).

It was found that one of the conductors might be replaced by a core of iron, inasmuch as the mutual attraction between the iron core and the coil could be made to serve in place of the attraction between the two secondary coils, and with greater effect so long as proper relations were maintained to carry out the same mode of operation. If a disc of iron be surrounded by a copper band and this with another conductor at an inclination to the first, the passage of a current through the outer coil

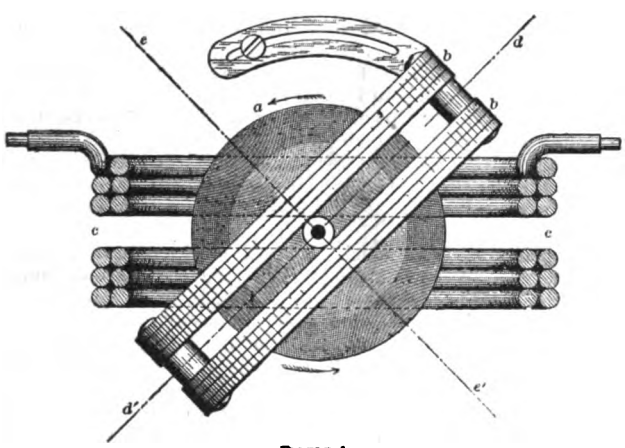

FIGURE 1.

will, by the action of the secondary currents set up in the short-circuited coil, produce a rotation of the disc; and the torque exerted is approximately proportional to the square of the current, so long as the rate of alternation is maintained approximately constant.

Referring to the diagram, figure 1 *a* is a flat ring of soft wrought iron mounted on a light disc of brass or aluminium, rigidly attached to a slender steel shaft,

b b are copper plates punched in the form of a flattened oval and riveted together at the ends, placed so as to surround the disc closely without touching it. These are adjustable in position with respect to the coil, *c c*, which surrounds the whole. When in the position shown, the rotation of the disc is in the direction of the arrows, and the torque is greatest when the plane of the coil shown by the line *d d'* is at an angle of 45deg. to that of the coil, *c c*. If while the current is passing through the coil the position of the plates, *b b*, is changed gradually to *e e'*, the speed of rotation of the disc diminishes until an angle of 90degs. is reached, and beyond this the direction of rotation reverses, reaching maximum speed again at 45deg. on the opposite side.

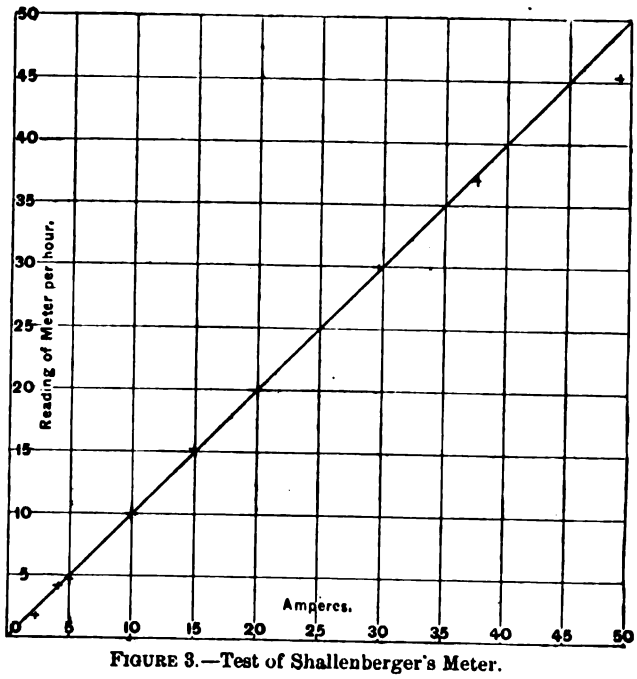

FIGURE 3.—Test of Shallenberger's Meter.

In applying this to the meter only a few degrees movement of the secondary conductors, *b b*, is required for the necessary adjustment.

This arrangement was selected from a large number of others

Digitized by Google

because of its ease of construction, the small self-induction it introduces, and its ease of adjustment.

The maximum torque is exhibited at an angle between the coils of 45deg., while at 0deg. and 90deg. it disappears altogether. When the angle is 0deg., the coils, being parallel, have a maximum mutual induction, but no torque is exerted; and at 90deg. no current is induced in the secondary coil, and consequently there can be no torque in that position.

In order that the speed of the disc may be proportional to the current, it is necessary that some resistance be offered to its motion, which bears the same relation to the speed as that of the torque to the current, and the simplest means of doing this is to attach to the same shaft on which the disc is carried a suitable number of light vanes, whose motion is opposed by the resistance of the air as the disc revolves. This resistance is found to vary almost exactly in the proper ratio, and consequently the revolution of the disc is as nearly as possible proportional to the strength of the current. The rotations of the dics are counted by a train of wheels connected with an indicator similar to that used for gas meters, and showing ampere hours. The accuracy of the instrument is affected slightly by changes in the rate of alternation of the current; but since in practical electric lighting the rate of alternation is maintained nearly constant, the error due to this cause is quite insignificant, being less than proportional to the number of alternations. The adjustment to the exact speed required is made by changing the angle of the secondary coil; but in practice the instrument is made very nearly correct as it leaves the factory, requiring only slight correction.

TEST OF 40 AMPERE METER.

Current in amperes.	Reading of meter.	Percentage of error.
2·06	1·6	
4·02	4·08	+1·2
5·00	4·95	—1·0
9·9	10·02	+1·2
15·0	15·1	+0·7
20·0	20·0	0·0
29·7	30·0	+1·0
37·4	37·0	—1·1
	Overloaded.	
49·3	45·4	—7·9

The accompanying chart and table show the operation of a 40 ampere meter, with currents varying from the smallest capable of turning the vanes and overcoming the slight friction of the bearings, to an overload of 25 per cent. Currents are measured on the horizontal line, and the corresponding readings of the meter are shown by the vertical distances. It will be seen that the departure from the theoretical straight line representing the mean performance of the meter is very slight, and in no case within the working limits reaches 2 per cent., except at starting point; while at 25 per cent. overload, the proportional rate only falls off 7·9 per cent.

The ease with which this meter may be adapted to circuits of different capacity is obvious. By interposing between the meter and the circuit to be measured a small converter, the current may be reduced or increased in any ratio, and since the energy transformed by such converter is only the amount required in operating the meter, namely, about one-eighth of one per cent. of the energy measured, the dimensions of the converter may be very small, and consequently but very little is added to the cost of the simple meter. By changing the ratio of this converter any capacity may be given to the meter, so that the same instrument may be used to measure ten lights or 10,000 lights within the same percentage of accuracy, and without change in its onstruction.

There is, however, one feature worthy of notice in this connection, namely, the point at which the meter will begin to turn, or, in other words, the percentage of its full load at which the registering of the current begins. This, in the 40 ampere meter already mentioned, is 1½ amperes, or say three per cent. of the rated capacity. While this represents only one or two lamps on a 40 ampere meter, and only one lamp on a 20 ampere meter, it will be seen at once that on a meter for 1,000 lamps the same proportion would give 30 lights required to start the counter.

In order to overcome this difficulty for the larger sizes of meters a shunt coil is provided, which, with a current almost inappreciable in amount, charges the inducing coil of the meter to a degree sufficiently barely to overcome the inertia and friction of the vanes, and in this way the large meter may be made to start on less than one per cent. of its full load as easily as the small meters start on three per cent.

There are certain cases in which it is very desirable, even where a large number of lights are installed, to measure a comparatively small proportion of the total current. Lamps are sometimes used for watch lights and other purposes, while the main body of the lamps are or are not in operation, and it is for this reason that the shunt coil is applied. Its operation may be made as sensitive as the conditions require.

The greater simplicity of the meter having a direct coil only, both in its construction and connection in the circuits, makes it preferable not to employ the shunt coil on any of the smaller sizes—namely, below 40 amperes. But it is evident that in special cases where it is desired to measure accurately the widest possible range of current the shunt coil can be employed with advantage.

Practical tests have shown this meter to be thoroughly reliable in its action, and with the exception of some minor details in the construction, no serious difficulties have presented themselves at any time. The meter as now manufactured for practical use seems to fill the requirements very satisfactorily, and has given no cause to doubt its entire reliability within limits of error much smaller than have hitherto been obtained in ammeters, voltmeters, and similar instruments.—*New York Electrical Engineer.*

ELECTRIC LIGHT APPLIED TO NIGHT NAVIGATION UPON THE SUEZ CANAL.*

BY R. PERCY SELLON.

I.—The period embracing the concluding years of the last decade, and the first years of the present one, during which a grave commercial crisis made itself felt not only in this country, but throughout industrial Europe, witnessed upon the great maritime highway which separates the eastern and western hemispheres a rapid increase of traffic and growth of activity.

In 1870, the year following the opening of the Suez Canal, 496 vessels of all kinds availed themselves of the facilities which this new highway to the East afforded. Two years subsequently—in 1872—this number had reached over 1,000. In 1878 the number was 1,593, and by the year 1885 it had more than doubled itself, reaching the remarkable total of 3,624 vessels, representing a gross tonnage of 9,000,000 tons.

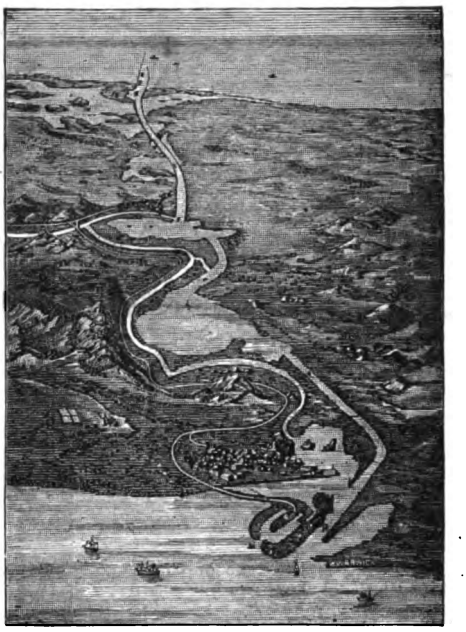

FIG. 1.

This active traffic, however, soon gave rise to difficulties of various kinds. Shipowners complained of delays in making the passage of the canal, delays which became more and more marked as the number of vessels using the canal increased. The channel proper being insufficiently wide (except at the "tying up" stations, which are placed every five miles apart) to admit of vessels passing one another, it becomes necessary for any vessel to "tie up" in accordance with signals from the nearest station—these stations being all in telegraphic communication with one another—while any vessel coming from the opposite direction gets past.

This in a canal 87 geographical miles long, and where the speed (except in the open Bitter Lakes) is not allowed to exceed six miles an hour, means constant delays at "tying-up" stations, the delays naturally increasing directly in proportion with the traffic.

Then a further cause of delay lay in the fact that vessels could only proceed by day, anchoring at either entrance to the canal—Port Said or Suez—or "tying-up" at the nearest station, if in mid-channel, from sunset to sunrise. Thus we find that in 1885 the average time consumed in making the passage of the canal amounted to 43 hours, though it frequently considerably exceeded this.

II.—To meet the difficulty thus presented, the Suez Canal Company set about various improvements; the cutting away of curves in the course, deepening and widening the channel at the tying-up stations, and finally instituted experiments to determine the practicability of navigation by night by means of the electric light.

The question of the practicability of successful navigation by night in the Suez Canal by means of electric light is not so simple as it would at first sight appear. To realise this, one must consider that the canal has but an average width of 22 metres (23¼ yards) upon the water line,

* Paper read before the British Association, at Bath.

Digitized by Google

with shelving sides, providing for a depth of water of some 8m. 70 to 9 metres (27—30ft.) in the centre, and with comparatively sharp curves at various points, as may seen from the accompanying plan of the canal; and that under such conditions vessels of 400ft. to 500ft. length, 40ft. to 50ft. beam, and drawing 25ft. of water, have to navigate the channel, encountering currents of varying force, the action of the wind, and greatly diminished influence of the rudder upon the vessel owing to the slackened speed.

It will be seen at once that under these circumstances it needs but a small deflection between the axis of the vessel and that of the channel to render the vessel liable to run aground. No small amount of judgment and experience thus becomes necessary on the part of the pilot who accompanies each vessel through the canal. The problem was, to reproduce by electric light the conditions requisite to enable the pilot to successfully navigate during the night.

These experiments extended over the greater part of two years, with the result that in December of 1885 it was decided to allow vessels of war and those carrying mails, if furnished with electric lights in accordance with regulations laid down by the canal company, to proceed by night between Port Said, the Mediterranean entrance to the canal, and kilometre 54, about one-third of the distance along the canal.

The first vessel to avail itself of this permission was the ss. "Carthage," of the Peninsular and Oriental Steam Navigation Company, in the month of April, 1886, followed shortly afterwards by others, the prescribed passage being made by night by means of the electric light with perfect success.

These and subsequent trials encouraged the Canal Company to extend its authorisation to vessels of all kinds; and, at the same time, by providing beacons and light buoys to guide the vessels in their course by night, to permit of navigation throughout the whole length of the canal.

factured, as are also the electric lamps and other electrical apparatus, by the Anglo-American Brush Electric Light Corporation, Limited, of London. The engine and dynamo are fitted upon a cast-iron bedplate common to both. To ensure reliability of operation, and minimise labour in attendance, the speed of engine and dynamo is reduced to 600 revolutions per minute, at which speed the latter is capable of yielding an output of 65 volts × 70 amperes of 4,550 watts. This provides for a light in the projector search light equal to 12,000 c.p., and at the same time supplies current for the automatic lamp of 6,000 c.p. over the bridge, when this latter is in use.

The projector search light, fitted upon its platform and fixed during the passage through the canal to the stem of the vessel as near to the water's edge as possible, as shown in the accompanying diagram, is used to light the course of the vessel to a distance of 1,200 metres (1,300) yards ahead.

Actually, the firm of contractors above mentioned have heard, from recent advices from the canal, that this light enables the pilot to see clearly as far as 1,600 yards ahead.

The projector proper, which is in many respects similar to the type in use for signalling and search purposes on war vessels, consists of an electric lamp of 12,000 c.p., the light rays from which are concentrated upon a spherical silvered mirror, made by Messrs. Chance, of Birmingham, fixed at the back of the instrument; this mirror reflects the rays, rendering them parallel, and projects them forward in a cylindrical beam; they are then made to pass through a series of plano-cylindrical lenses fitted in the front of the projector, so that the beam emerges in the shape of a fan, flattened horizontally.

This beam, diverging to an angle of 20deg., can by means of suitable adjustments provided for the purpose be directed upon any desired spot. At a distance of 1,200 metres ahead of the vessel the full width of the canal and the banks on either side, composed of the *débris* excavated from the channel, are illuminated as clearly as by day.

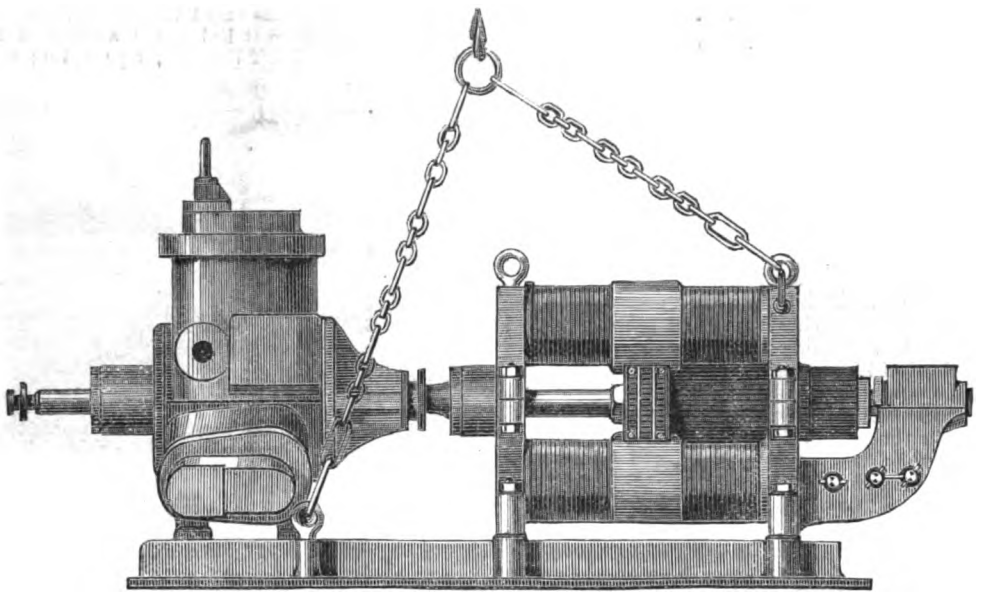

FIG. 2.

III.—The following is the text of the regulations on this subject issued by the Suez Canal Company in February, 1887:

"(i.) From 1st May, 1887, steamers will be allowed to pass through the canal by night, subject to the same conditions as those which hold for navigation by day, and subject to the following further restrictions:

"(ii.) Steamers intending to pass through the canal by night must satisfy the company's agents at Port Said or Port Tewfik, that they are provided: (1) Forward, with an electric search light throwing a beam 1,200 metres; this search light must be placed as close as possible to the water line. (2) With an electric lamp and a reflector suspended above the bridge and capable of lighting a circular area of about 200 metres diameter.

"The agents of the company will decide whether the apparatus fulfils the requirements of the regulations, so that vessels provided with them may without inconvenience be authorised to navigate the canal by night.

"(iii.) If a vessel proceeding by night receives the signals to 'tie up,' it must, immediately upon this being effected, extinguish its electric lamps, retaining only the regulation signal lights indicating that it is 'tied up.'"

IV.—Passing now to describe the apparatus designed to fulfil these requirements. This consists essentially of three parts:

(1) The source of electric power—a steam-engine and dynamo-electro generator.

(2) A projector search light fitted upon a platform large enough to accommodate a man to manipulate the light: the whole being attached to the stem of the vessel forward and close to the water's edge.

(3) An automatic electric lamp suspended above the bridge and capable of illuminating a circular area of 200 yards diameter round the vessel.

The accompanying diagrams illustrate the various pieces of apparatus, and also a vessel so fitted traversing the canal.

The engine is of Brotherhood's 3-cylinder type, fitted direct by means of a flexible coupling to a Victoria dynamo-electro machine, manu-

An attendant, seated upon the platform, attends to the manipulation of the carbons of the electric lamp, and at the same time regulates the position of the beam of light, elevating, depressing, or deflecting it on either side in accordance with the orders of the pilot upon the bridge, with whom he is generally in telephonic communication.

The placing of the projector close down to the water's edge, where the light is hidden under the bow of the ship, is a point of essential importance, since any direct rays of light intervening between the pilot and the distant object illuminated by which he steers the vessel, serves to dazzle his eye.

The automatic electric lamp is of 6,000 c.p., enclosed within a lantern, and fitted with a concave reflector, arranged to concentrate the light round a circular area of 200 yards. In this way the area illuminated comprises the whole deck of the vessel and the canal and its banks immediately on either side. This light is only intended for use when passing other vessels "tied up" at the stations, or to provide light around the ship when "tying up" so as to allow another vessel to pass.

V.—A large majority of mail and passenger steamers are now fitted throughout with the incandescent electric light. In fact, electric light has come to be regarded as a *sine qua non* to any first-class passenger vessel.

In such cases, the steam-engines and dynamo generators already in the ship are usually utilised to supply electricity for the special Suez Canal lamps, which latter may form part of the permanent equipment of the vessel. This is the case with many of the vessels of the P. and O., the Orient, and the North German Lloyd lines of steamers. On the other hand, where a vessel which is not already fitted with the electric light desires to avail itself of the permission to traverse the canal by night, it can hire the necessary plant at either entrance to the canal.

The *modus operandi* is as follows:

Several of the prominent coaling firms at Port Said have possessed themselves of a certain number of sets of portable electric lighting

Digitized by Google

plant for the Suez Canal. These they hold in readiness for vessels to their consignment who may require the light, making an average charge for the use of this, which at the present time amounts to £10 per vessel for the passage through the canal.

On receiving a given signal from an incoming vessel that electric light is required, a tender is sent out to meet it, having on board the necessary portable plant. Coming alongside, the engine and dynamo are quickly hauled up, dropped on to some convenient spot on deck, and the engine connected with the nearest convenient steam-pipe—generally one belonging to the system in use for steam-winches forward; the automatic lamp slung up over the bridge; the projector floated round and made fast to the stem; temporary conducting wires run from the dynamo generator to the two lamps; and in less than an hour from the time of the tender coming alongside, the ship is ready to make the passage of the canal by night. On reaching the opposite end of the canal the electric light plant is disembarked, and the vessel proceeds on her way.

It is with such a portable plant as has just been described, and which the accompanying diagrams illustrate, that the author was engaged in trials upon the Suez Canal in the early part of last year.

VI.—To realise the development which has followed upon the introduction of electric light for the purpose of night navigation, and to appreciate how real has been the benefit flowing therefrom, we have only to examine the following figures, which illustrate the number of

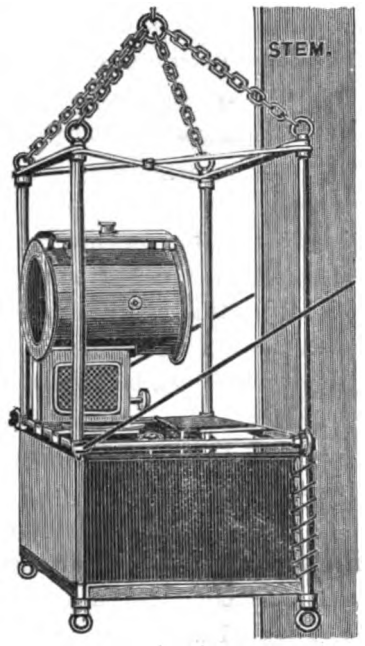

FIG. 3.

vessels which have passed through the canal in this way at different periods since the first authorisation to use electric light in December, 1885, and which define the percentage of vessels so using the light in comparison with the whole traffic on the canal:

PERIOD.	Number of Vessels which passed through the Canal by Night by means of Electric Light.	Percentage of these to the whole Traffic.
From December, 1885, to 1st March, 1887—viz., 15 months	25	70 per cent.

March ,,	111	34½ ,,
May ,,	139	43 ,,

VII.—It remains but to enquire "What are the advantages arising out of the use of electric light on the canal, which have led to so striking and rapid a development?"

To the Suez Canal Company, on the one hand, it means that the capacity of their canal has been rapidly, effectively and economically increased by nearly 50 per cent., an increase attained without an army of labourers, without a host of dredgers, without a lapse of years, without interruption to traffic; that while a traffic which reaches 7,000,000 to 8,000,000 tons is now actually attained, an increased traffic, equal to 11,000,000 to 12,000,000 tons per annum can be accommodated, while offering not only equal, but greater, facilities to shipowners making use of the canal; that in the meantime the canal company, relieved of the pressure put upon them from outside, can pursue their works of improvement with greater deliberation and economy.

It is only fair to say, however, that the Suez Canal Company on their side have displayed a ready initiative and far-seeing confidence in the success of the scheme, by putting down a large number of light-buoys to indicate the course by night in the Bitter Lakes, of guiding lights along the banks, and an extensive gas works at Ismailia for supplying the above with gas at a time when to many an extended adoption of the electric light by shipowners seemed problematical. To shipowners, on the other hand, it means in the first place a saving of time. I pick up the *Official Gazette* of the Suez Canal Company, published at Paris, for January of this year, and read as follows: "The 'Moskwa,' of the Russian mercantile marine, using the electric light, entered the Suez Canal on 12th December at 6.15 p.m., and passed out on the following morning at 8.45 a.m.; total time occupied in the passage 14½ hours."

In another portion of the same *Gazette* for the same month I read as follows: "The mean time occupied in making the passage of the canal for all vessels during the month of November last was thirty-six hours ten minutes."

Taking as average periods for the passage of the canal, eighteen to twenty hours for all vessels using electric light, and thirty-five to forty hours for all vessels not so provided—figures which the canal company's official *Gazettes* and the author's own experience upon the canal prove to be in accordance with actual facts—we find that the saving of time resulting from the use of the electric light approaches the twenty-four hours of a whole day. What does this saving in time represent?

For vessels carrying cargo exclusively, of an average tonnage of, say, 2,500 tons, interest on capital, demurrage, coal consumption, wages, and provision for the crew represent a sum of £30 to £40 per diem

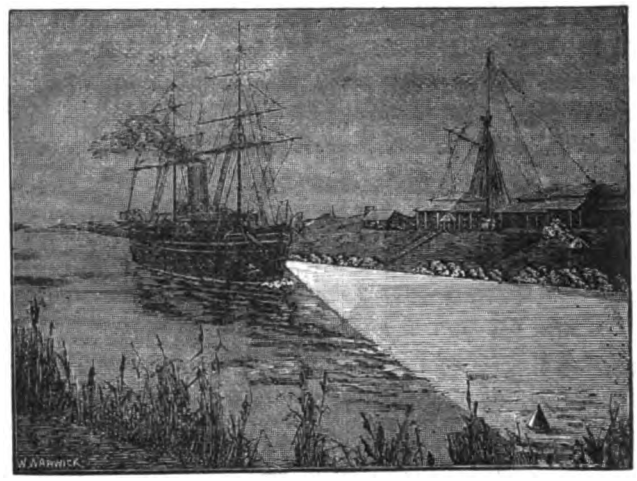

FIG. 4.

For vessels of war, where rapid communication between England and her possessions in the eastern hemisphere, or the scene of her frequent wars in the Soudan or Africa is by way of the Suez Canal, the saving of 24 hours may entail consequences not easy to calculate.

For mail and passenger boats the results are naturally more marked than in the case of cargo steamers.

An interesting example of the practical value of the electric light is afforded in connection with the transport of mails to the East during the time when the cholera in Italy led to enforced quarantine of all vessels from Italian waters communicating with the shore in Egypt. It has been customary for the mails brought by the Peninsular and Oriental Company from Brindisi to be landed at Alexandria and sent overland to Suez to save the time taken by vessels in the canal. In order to avoid the delay of quarantine, the mail boats of the Peninsular and Oriental Company proceeded, without unshipping the mails, direct through the Suez Canal by means of the electric light, reaching Suez and transhipping the mails within the same time as that occupied by the overland route in the ordinary way.

The cost per 24 hours of a first-class vessel of this kind, including insurance, demurrage, interest on capital, coal, wages, provision for the crew, and provision for the passengers, cannot be put down at less than £100 to £150.

Taking as an average saving effected by each vessel traversing the canal by night, a sum of £70 to £80, a figure which, in view of the proportion of mail and first-class passenger-carrying vessels to the whole traffic on the canal is well within the mark; and taking 40 per cent. of the vessels entering the canal as making use of the electric light, a percentage which it will be borne in mind has already been exceeded; we find that for 1,200 vessels having so availed themselves of the electric light, the annual saving to maritime commerce will amount at a minimum valuation to close upon £100,000.

And to this must be added the personal comfort to all concerned derived in escaping some period of the excessive heat experienced upon the canal by day, the glare from the banks of yellow-white sand, the tedium and monotony of the slow passage through a wide expanse of barren desert.

In conclusion, without considering to what development this use of the electric light may ultimately attain in an age in which increasing efforts are being made to economise time and space, it has been attempted, by the foregoing few facts and figures, to illustrate the advance recently made in one adaptation of electricity to the service of man.

NOTICE.

With our issue of January 6 we gave a Portrait of E. GRAVES, ESQ., *President of the Society of Telegraph Engineers, and stated our intention of giving a series of Portraits of eminent Electricians of the century. In fulfilment of our promise we have already issued a Portrait of* W. H. WOLLASTON, M.D., F.R.S., *and on April 20th we gave that of* SIR HUMPHRY DAVY, F.R.S., *whose fame as an electrician is still more prominent than that of* WOLLASTON. *Portraits of Past Presidents of the Society are in preparation, and we hope soon to have ready that of* PROF. D. E. HUGHES, F.R.S.

LIGHTNING CONDUCTORS.

Perhaps the most entertaining part of the late British Association meeting at Bath was during the discussion on Lightning Conductors on Tuesday morning, Sept. 11, in section A. The discussion partook of the nature of a pitched battle between sections A and G: the champion of section G being its president, genial Mr. Preece, who was opposed from section A by Prof. O. J. Lodge. The latter gentleman, in his lectures before the Society of Arts in the early part of the year, had put forward views derived from the results of experiments that were somewhat startling, and it was these views that were in dispute. Mr. Preece, Mr. Symonds, and others did not agree with them, and it was thought the British Association meeting would present an admirable opportunity for both parties to put forward their views, and attempt to reconcile their differences. The popularity of the speakers and the interest in the subject was evident from the crowded state of the meeting. The result (as will be seen from the full report—a portion only being given in this week's issue) might be termed a drawn battle, both sides having scored some points, the general idea being that Prof. Lodge had fairly held his ground but had not routed his antagonist. Several points were, so to speak, reserved for written communications to the press, and some were not touched upon at all. One of these latter it may be well to call attention to here. Before Snow Harris commenced protective operations on the Royal Navy, the damage done by lightning was known to be considerable, and we venture to think the comparison between the damage done in a similar manner since protection had been effected, would have been both instructive and interesting. Has there been one single proved case of the loss of a vessel since because of lightning stroke? No doubt vessels leave port and are never again heard of, and it may be the total loss is due to lightning stroke, but of this we know nothing and can know nothing. The disaster is more likely to be due to the bursting of a boiler. However, no point was made by either party as to the effectiveness or the ineffectiveness of the method of protection adopted on board ship. Come we then more directly to the question under discussion, the protection of buildings on land. Mr. Preece contended that whenever an accident happened it was easily traceable to negligence, some part of the apparatus was defective, or erected in a manner contrary to that suggested by the report of the Lightning-Rod Conference. In this report the best experience of the age is to be found, and if its rules are followed there will be, maintained Mr. Preece, absolute safety. Prof. Lodge, on his part, referred to Melsen's work at the Hotel de Ville at Brussels as having been looked upon as the most

Digitized by Google

perfectly protected building in the world, yet an accident had happened at Brussels, though the details were not generally known. It should be pointed out that Prof. Lodge's suggestions as to house protection are but modifications of those of Clerk-Maxwell's cage system. We incline to the opinion that a house protected by flat chimney plates at the top of the chimney, armed around the edges with barbed wire, and connected to barbed wire protectors along the ridges and eaves, continued by a number of galvanised iron wires down the sides of the house to good earth, would be more effectually protected than by the single lightning rod which is but too frequently used.

We have already given Prof. Lodge's lectures and some slight comments thereon, so that it is not necessary to traverse the ground again. One of the most important points in Prof. Lodge's experience brings into question what may be termed the time function, and we must confess at present to being in a state of doubt as to the accuracy of any deductions which may be drawn about the value of iron *versus* copper. Advanced electricians can understand the argument of Prof. Lodge, but engineers and architects may prefer analogy. A heavy blow given to water in a pipe will most probably fracture the pipe and the water will escape where it is not wanted, is perhaps nearly analogous to what Dr. Lodge means when he speaks of the lightning stroke, instead of being carried safely to the ground by the conductor, going off by a side flash and meandering around to some distant pipe or water-butt. If instead of a blow, a steady pressure be applied to the water, such pressure will be duly transmitted, and so, no doubt, in the case of electricity, when the current will be duly conducted. But why the copper, in Dr. Lodge's experiments, should have acted more unfavourably than iron is not clear. The opposite might have been expected. Nor are we much helped by the suggestion that it is not so much sectional area as surface action which has to be considered. One point, we think, Mr. Preece carried without doubt, that the lightning flash could not be considered oscillatory because the discharge of a Leyden jar was oscillatory in its action. The most important practical outcome of the discussion is whether we can in any way cheapen the protection of buildings from lightning by adopting Prof. Lodge's suggestions, provided the conclusions of competent authorities are that the system is safe. It was laughingly stated that the safest building would be one constructed wholly of iron, without openings—other, we presume, than a descent by steps to an entrance effected under the floor. This is carrying the cage system to extremes, and is not practicable. While it is cheaper to insure rather than protect, protection will be the exception and not the rule. Otherwise it would pay the insurance companies to carry out a system of protection for themselves. The weak point in the present system is this possibility of a side flash, and though whenever it occurs it is said to be due to negligence, it does occur, and occurs in places which were supposed to be perfect. What the continued controversy through the medium of the press will bring forth is unknown, but it will be carefully followed, as is every scientific discussion which has so visible and immediate a connection with the saving of money, property, and life.

INCREASING ACTIVITY.

The passing of the amended Electric Lighting Act seems to be not without avail. Increased activity is arising on every hand, and this season bids fair to be one of the most important in the development of the electric lighting industry in Great Britain. We chronicle this week the start that is to be made in taking up the streets at Whitehall early next week for laying the electric supply mains in that district. The Kensington Company is also extending its mains into the great residential district of Knightsbridge. Both of these stations are on the battery-transformer low-tension system. The London Electric Supply Company are rapidly pushing forward the work at Deptford, which is to supply 500,000 lights eventually, to the City and West End, on the alternate-current-transformer high-tension system. In Liverpool—our next largest English town—great activity is being shown by the Electric Supply Company, who have completed arrangements for extended supply of a large number of lamps to the most populous district of Liverpool, and the work is now in hand. Bradford, Brighton, Hastings and Eastbourne are extending their existing supply. Besides this, Barnet and Buckingham have central stations in progress. Bath is being fitted, Chatham and Gravesend have work in hand; while Dublin, Cheltenham, Exeter, Dover and Folkestone, Swansea, Richmond, Norwich, Poole, North Shields, Otley, and Fleetwood—to mention a few names of those who have lately inquired for or invited tenders—amongst numerous other towns, have been stirred with the desire to possess themselves of the benefits of this, the greatest and most beneficial of the latter discoveries of science. While in America there is hardly a town of 5,000 inhabitants that does not boast its central station, nor scarcely one of 10,000 that has not, at the present time, an electric railway in debate, if not in operation or course of construction, we, in England, have continually been feeling ourselves somewhat left behind in the use of our own inventions and perfections. At last, however, the air clears, and activity begins to show itself all round. We are at

Digitized by Google

least—we may congratulate ourselves—never likely to have to put up with the hideous mixture of posts, poles and wires of all descriptions, hanging in festoons to the imminent danger of the public, too often heard of in America, nor to disfigure our urban streets with innumerable poles; but with the inauguration of the finest systems of underground distribution science can now afford us for our light and our power, and with electric accumulator cars for our tramway service, now, we hope, happily to extend in every direction, we shall not fail to reap in beauty and convenience the reward of our period of waiting for the electric light.

ELECTRIC LIGHTING IN AMERICA.*

BY PROF. GEORGE FORBES, F.R.S.

Having since the last meeting of the British Association had occasion to pay two visits to the United States, and while there to study very carefully the systems of central station lighting in vogue, and also to compare what was being done there with what was being done here, and being, further, able to compare the state of central station lighting in America as it is at present with the condition it was in four years ago, when this association visited America, I felt it was a sort of duty I owed to the association to bring before it some account of what I had seen, believing it would be especially interesting at the present moment, when there are signs of a very great determination on the part of the public in this country to have electric light supplied to them from central stations. At the same time I felt considerable diffidence in bringing before you the facts which have been collected—not in the least because there is any want of facts, but by reason of their number, which renders it difficult to make a proper selection of the points likely to be of interest to the members of this section and to electric lighting engineers.

In the first place, remark has been often made to the enormous progress which central station lighting is making in America. At the moment one lands one is struck by it; and when one lands, upon returning to England, one is equally struck by the dimness of the lighting in our country. In America there is not a single town with which I am acquainted where you can walk in the streets at night without seeing an abundance of arc lamps. I am not simply speaking of the principal towns, like New York, Philadelphia and Boston, but of the most out-of-the-way places in the most distant States, where gas has never penetrated. There electric lighting has fixed its position, and it is being used frequently. Not only has the electric light been adopted in these remote towns, but other developments of electricity have followed. As an illustration of the kind of places to which electricity and electric light have found their way, I may mention that I have a paper here published in a village in Alaska, one of the least developed of the territories of the United States, and the same number of this paper, which treats of the introduction of electric lighting in a scientific manner, treats also of the advisability of passing a law to expel Indians from the city at nine o'clock every evening.

At the time I was attending the Electric Light Convention at Pittsburg last February, it was estimated that there were 300,000 arc lamps lighted from central stations in America. The progress of arc lighting of late years, however, has not been so striking to an Englishman as formerly; the arc light was firmly established when the British Association visited America four years ago. The progress which has struck us most of late has been the progress in incandescent lighting from central stations. At the same time—I am speaking of February of the present year—it was estimated that there were 2¼ millions of incandescent lamps in use in the United States; and the rate of manufacture has increased enormously, to my knowledge, since that short time ago. There are four or five manufacturing places in the United States at this moment, each capable of turning out 10,000 incandescent lamps every day, and I have no doubt that the annual rate of production now is to be counted by millions. Of incandescent central stations there are two classes, those upon the three-wire system, in which a continuous current is supplied to the main conductors over a town and the lamps are connected by branches to the system of positive, negative, and intermediate mains. That is the system which is so largely adopted in all the Edison stations; it was the Edison stations which interested us most in 1884, and they have continued to advance and have developed the three-wire system to a very great extent indeed.

But I feel quite sure that the greatest progress that has been made in central station lighting in America since the association visited it, has been by the work done by Mr. Westinghouse in that country. One of Mr. Westinghouse's agents in passing through Europe saw the experiments which had been made by Messrs. Gaulard and Gibbs in this country on the use of alternating currents to distribute the electric light. By means of this system an alternating current of very high tension could be passed along the streets over conductors of very thin diameter and very cheap to construct, and at the consumer's premises this high tension dangerous current could be reduced in tension by means of an induction apparatus called a converter, and passed into the house at a harmless pressure suitable for the ordinary incandescent lamps.

And here I may say that I never fail to take any opportunity which presents itself to me to say what I feel with regard to the energy and determination with which Messrs. Gaulard and Gibbs, in spite of the most adverse criticism which was universally passed upon their first attempts, persevered and continued to improve their invention, and eventually proved to the world that it was possible to have a commercial system of lighting by means of these converters.

Mr. Westinghouse, on seeing this system, took it up, and the result is that he has established, in the course of a very few years, an enormous business in central station work. It is now a possibility in America—not a possibility merely, but a thing of daily occurrence—for a town to write an order for a central station, which has to be sent out at ten days' notice. They do not order a dynamo, set of conductors, and other apparatus all independently, but complete central stations are being sent out from Mr. Westinghouse's works. In December of last year the manufacturers of incandescent lamps drew out a long list of the number of lamps being used in different parts of the country, and I have abstracted from that list some notes which show that at that time Mr. Westinghouse's alternating current system was supplying 153,285 lamps, occupying 152 distinct plants, and 42 of these had plant for more than 1,000 lamps. At the present moment they have set up 110 central stations with 191,000 lamps.

It has been said that in this country we do not go ahead so much as they do in America, and various reasons have been suggested to account for this. Prof. Ayrton's most admirable reason seems to go a long way—namely, that there are two definitions of inertia: the English, which is that inertia is a resistance to motion, and the American, that it is a resistance to stopping. But I must say that in electric lighting we certainly have been stopped a great deal by what I might almost call the iniquitous Electric Lighting Act. And I regret extremely, in the interest of the public and of electric lighting generally, that an Act has been passed this year which has not yet put electricity on the same footing as gas. This is a matter for extreme regret to all those who have the ultimate benefit of the electric lighting industry at heart, for that Act will delay the due recognition of the value of electric lighting.

But I must say that I do not think the Electric Lighting Act is the only thing which has delayed our progress, because I see that in electric traction and other developments of electricity also the Americans have gone ahead with great energy, and I certainly do not put it down to want of capacity on the part of our inventors, for I find that the best dynamo machines as well as arc lamps were all designed originally in England. But, with inferior machines and lamps in the States, I have noticed that they are determined, as long as they have something which they know will work, to make it work well, and be ready in the meanwhile to take up something else. I think, therefore, that is not in the inventors that we have to look for go-aheadness, but to men of capital who are also technically instructed. I think it is technical instruction among the moneyed classes that has developed electrical engineering so much in America of late years.

I will now try to describe some of the leading features of the Westinghouse central stations which I visited, and perhaps this may be of use in helping us to draw some conclusions as to the lines in which we are to develop electric lighting in our own country. I do not in the least wish to say that the American arrangements are the best. In many points I see objections, and many where I should wish to see improvements; but we have in the system which I am going to describe a thoroughly successful working arrangement, and although we in this country may not adopt all the points of such an arrangement, still I feel that it will be of use to us to realise what is being done on the other side. It is a curious thing, for example, that in America there is hardly any work being done with accumulators. There is an example where we have led the way, as compared with the Americans. I was struck with the fact in 1884, and still more in the present year, that accumulators do not seem to work in the American atmosphere; at any rate, people have been importing numbers of accumulators, and yet they are not recognised as the generally satisfactory apparatus we have come to regard them; they are looked upon there as being as uncertain now as they were with us four or five years ago.

The Westinghouse system, then, chiefly depends upon the apparatus which has been called by the names secondary generator, transformer, or converter; "converter" is the term generally adopted in America. This is simply an induction apparatus with two coils, a primary and a secondary. The primary coil, in contradistinction to the ordinary Ruhmkorff induction coil that we have known so long, is of high resistance, with a large number of turns on the primary and a small number on the secondary, which goes to the lamps. The alternating current produces induction in passing through the primary, which reacts on the secondary, thereby producing a current of low tension going into the houses. The primary coil and the secondary are completely separated, and when properly constructed it is quite impossible that the high tension current can ever reach the secondary circuit, so that the consumers of electricity have nothing to fear from the dangerous current which is distributed from the central station.

A central station contains furnaces and boilers, engines, alternate current dynamos, exciting dynamos, switch-boards, testing instruments, repairing shop and stores. The scheme of arrangement of the mechanical and electrical parts is generally the same in every station.

The wires led out from the station are carried generally on poles as feeders to the separate districts. The secondary wires inside the house, to which the lamps are attached, are laid in the usual manner, and are connected to the secondary poles of the converter. The dynamos are run day and night without cessation; charges are made by contract or by meter.

We hear a great deal of the imposibility of running machinery day and night without breakdowns, and I cannot help rather endorsing the opinion I heard universally expressed in America—that this fear has been enormously exaggerated in this country. When we see our huge 10,000 to 15,000 h.p. engines traversing the ocean, performing their work for days and weeks without breakdown of any sort, it seems absurd to expect that where we are able to subdivide our power, as in a central station, there should be any serious breakdown in a properly organised system. As a matter of fact, I assure you that in America central stations have been running (without accumulators) for years and years, and it is a matter of the utmost rarity for an accident to arise of sufficient importance to stop the general lighting of the district. The Edison central station in Pearl-street, New York, which has been running many years, has, I believe, only once broken down, and that was an accidental occurrence due to too much current being turned on on a foggy day, and the experience of other central stations is to the same effect. The general view in America is that there is no danger of a breakdown ever happening in a properly organised station.

It happens that in the department of furnaces and boilers there is much of special interest in many of the Westinghouse stations. This arises from the fact that over a great part of Western Pennsylvania the fuel employed is the natural gas obtained from the wells in that region, and carried in pipes to considerable distances. But this is a feature so peculiar to the district that it requires only a short notice here. I may, mention, however, that I was surprised to hear Mr. Dowson say that he did not expect to see his gas used for the boilers of steam-engines. In Pittsburg they use gas as fuel in preference to coal.

The gas with its due proportion of air to produce the high temperature of a Bunsen burner, is admitted by pipes with a sufficient number of nozzles into a combustion chamber. Here the burning gas passed over a mass of bricks with ventilating spaces, and thence through the tubes of the boilers. The gas is nearly free from carbon, and the hydrogen, which is paramount, undoubtedly weakens the iron of the boilers; but practice shows that this action does not go far, and the iron acquires a final condition in which it does not deteriorate, but seems capable of indefinite use.

In the best stations the admission of gas and air to the furnaces is regulated by means of a valve controlled by a lever, which in its turn is subject to the pressure of the steam in the boiler. This automatic regulation is very perfect, so that the attendance of one man to the boilers and furnaces of a station with several thousand horse-power is quite sufficient.

As to steam-engines there is no need to say much, for I do not think the Americans can teach us anything about making steam-engines. But there are some points in connection with the class of steam-engine used which I think are of importance. The desirability of introducing large, powerful, slow-running engines which are economical in the consumption of coal into central stations has often been talked of. Practical experience, however, has decided the question for the present exactly in the opposite manner. It is found to be more economical and safer to have a number of dynamos in each station, each driven by a separate engine of high speed, the power in America being always transmitted by belts and not by countershafting. About the rights of this question there cannot be the slightest doubt. It has been proved over and over again by experience. At first sight it does not seem probable that a number of independent high-speed engines should be more economical or safer than a single large engine, say of the marine type. The explanation lies in the special conditions of central station lighting. Without dwelling upon the great loss of power due to countershafting with the large engine, it is only necessary to observe that the maximum load in a lighting station is many times as great as the average load. Thus, if the single engine be adapted for the maximum load, it is working underloaded during the greater part of the 24 hours. The consumption of steam in proportion to power developed is very high, and the engine is under these circumstances not an economical one. With the independent engines, on the other hand, none of them need at any time be working much under its best load, and when the load increases other engines and dynamos can be switched in, and they are thus always working at or near the most economical conditions.

It has been found from actual practice in electric light work in identical central stations that 20 per cent. more work is required in the case when countershafting is introduced.

It has also been proved, from the experience of numerous central stations, that during a considerable number of hours in the night the load on the engines and dynamos is only one-eighth part of the maximum load.

For these reasons it is found most economical to use with each dynamo an engine whose most economical load is something like 20 per cent. under the maximum load. Waste of steam is far greater with underloading than with overloading.
